

Preparing for your Professional Cloud Security Engineer Journey

Section 1: Configuring Access

In this module you'll learn about defining a high level plan for an organization's cloud identity and access management, which corresponds to the first section of the Professional Cloud Security Engineer Exam Guide.

Module agenda

- 01 Planning Cymbal Bank's cloud identity and access management
- 02 Diagnostic questions
- 03 Review and study planning

We'll start by discussing some different aspects of Cymbal Bank's identity and access management structure. Next, you'll assess your skills in this section through 10 diagnostic questions.

Then, we'll review these questions. Based on the areas you need to learn more about, you'll identify resources to include in your study plan.

Planning Cymbal Bank's cloud identity and access management

Google Cloud

Let's begin by exploring how a Professional Cloud Security Engineer would plan Cymbal Bank's cloud identity and access management.

Setting a secure identity and access foundation

- Managing Cloud Identity
- Managing service accounts
- Managing authentication
- Managing and implementing authorization controls
- Defining the resource hierarchy

Cymbal Bank is extending its on-premises office and data center infrastructure to connect into Google Cloud to support a hybrid cloud model. As a Professional Cloud Security Engineer, you play an integral role in securing the cloud environment and the data stored therein.

In the cloud, Cymbal Bank will leverage the shared responsibility model to secure its virtual infrastructure, workloads, and data on top of the hardware and physical infrastructure security provided by Google. You will help design their systems incorporating security features provided by Google Cloud along with the recommended approaches and best practices to ensure a layered defense in depth.

You will begin by helping them synchronize and federate their current identity management system to Cloud Identity. This will let employees use the existing Cymbal Bank authentication system to be granted access to Cymbal Bank's Google Cloud resources via their user or group identities.

You will also help Cymbal Bank define service account identities for their workloads running both on-premises and in the cloud to provide access to protected resources and data in Google Cloud. Those resources and data will be arranged in an organization hierarchy that aligns with their access control requirements and helps them achieve least privilege access control and separation of duties.

Synchronizing Cymbal Bank's identities to Google Cloud

One-way synchronization of LDAP or Active Directory (AD) identities using Google Cloud Directory Sync (GCDS)

- AD users and groups synchronized to Cloud Identity by GCDS on daily schedule after daily updates to AD system

Cymbal Bank will synchronize their on-premises Active Directory (AD) users and groups to Cloud Identity (CI) using the Google Cloud directory sync tool. They will set up a cron job to run the tool on a daily schedule right after the daily updates to the AD system to ensure any changes to organization users, groups, and group memberships are synchronized from the AD system into Google Cloud.

Cymbal Bank will then be able continue to use their existing Active Directory authentication system for which they have a long-term contract. This system is configured for multi-factor authentication.

Configuring Cymbal Bank's single sign-on to Google Cloud

SAML2 single sign-on configuration

- Federate using SAML2 for Single sign-on (SSO)
- Active Directory is the Identity provider (IdP) and Google Cloud is the service provider (SP)

☒ Setup SSO with third party identity provider

To setup third party as your identity provider, please provide the information below. ?

Sign-in page URL	https://sso.your-domain.com/auth
	URL for signing in to your system and G Suite
Sign-out page URL	https://sso.your-domain.com/logout
	URL for redirecting users to when they sign out
Change password URL	https://sso.your-domain.com/info
	URL to let users change their password in your system; when defined here, this is Shown even when Single Sign-on is not enabled.
Verification certificate	<div> <input type="button" value="Choose File"/> <input type="text" value="Certificate.pem"/> <input type="button" value="UPLOAD"/> </div> <p>The certificate file must contain the public key for Google to verify sign-in requests.</p>

Google Cloud

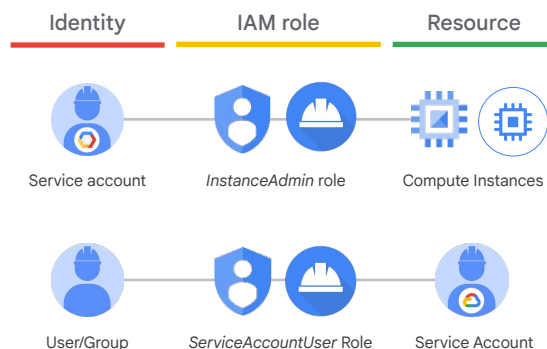

Cymbal Bank will synchronize their on-premises Active Directory (AD) users and groups to Cloud Identity (CI) using the Google Cloud directory sync tool and configure CI to use the corporate AD as a SAML2 Identity provider (IdP) and Google Cloud as Service provider (SP).

This will allow Google Cloud roles to be bound to their existing AD user and group identities and they can continue to manage the users, groups, and group membership as well as authentication for users and groups in AD.

Service accounts provide service access to Google Cloud

Service accounts used as service identities for workloads running in or outside Google Cloud

- Given access to resources like user and group identities
- Authenticate with private keys
- Leverage Google key management for most secure usage

Cymbal Bank will create separate service accounts for all their Google Cloud workloads running in Compute Engine VMs and GKE containers as well as for any on-premises workloads that require access to Google Cloud resources.

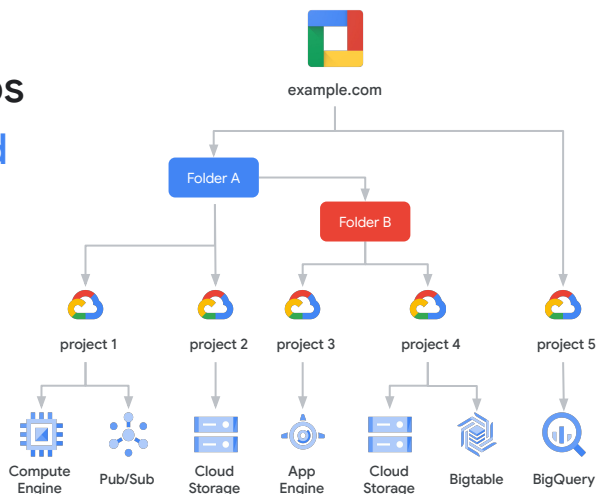

Cymbal Bank will primarily leverage Google key management (provisioning and rotation) for these service accounts to reduce risk of key exposure by using features such as GKE Workload identity and Workload Identity Federation.

They will prevent users creating service account keys with rare exceptions, use automated rotation of such keys when they do, and carefully audit that usage. They will also carefully control who has access to which service accounts and audit how they are used to ensure alignment with security best practices.

Organization hierarchy helps organize access control and policy for resources

Folders provide for flexible
hierarchy of Projects

- Organization policy and access control can be bound at any level and flow downwards

Google Cloud

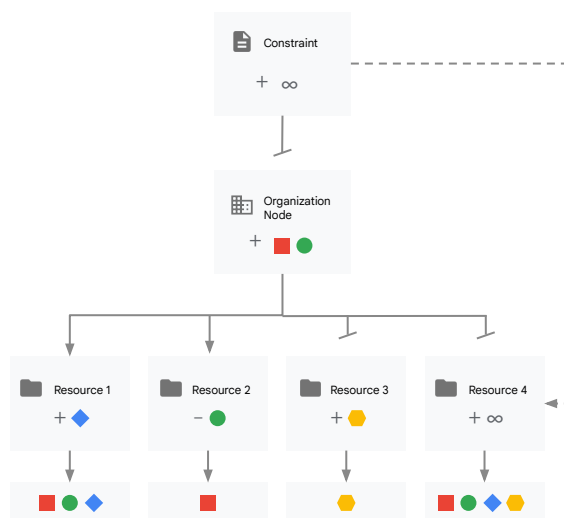

Cymbal Bank will create their Organization in Google Cloud with a Folder hierarchy aligning with their departments, teams, products and shared services. They will utilize separate projects for development, QA, and production environments.

Projects may or may not have standalone VPCs for workloads that require isolation, and there will be a set of development, QA, and production shared VPC host projects for cross-project communication.

Organization policy helps restrict to authorized usage

Organization policies composed of a set of organizational policy constraints can be bound at multiple levels of hierarchy

- Large number of optional constraint types across various Google cloud services
- Policies may be configured for inheritance down hierarchy or not
- With inheritance, ancestor policy constraints can be overridden or merged

Google Cloud

Cymbal Bank will utilize Organizational policy constraints in multiple policies bound at different levels of the hierarchy to restrict activity across projects to approved and expected services and processes.

They will set constraints on which services can be enabled in parts of the hierarchy as well as which regions or zones can be used. They will also set constraints around which identities from which domains can be granted access and how service accounts can be used.

Bind roles to identities to provide access to resources

Roles are collections of permissions which align with the required access for an abstract job function

- Facilitate least privilege access control and separation of duties
- Can be bound at organization, folder, project, or resource level and flows downwards

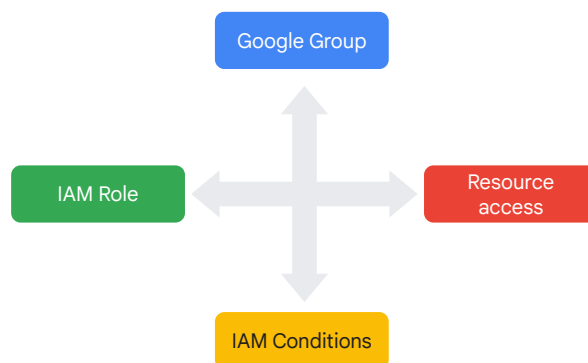

Cymbal Bank will primarily assign access by binding predefined roles to groups aligning with the principles of least privilege and separation of duties. They will always bind roles as low in the hierarchy as possible when the access is not required across multiple resources or projects. They will also partition access to minimize the damage any single actor can do.

Providing access primarily via groups rather than individuals minimizes maintenance as individuals join or leave teams or the organization, and reduces effort and complexity for auditing activity.

IAM conditions to control the where, when, how of access to resources

IAM conditions can be added to role bindings to control from where, when, and how the access can be used

- Allows for even better least privilege access control

Cymbal Bank will utilize IAM conditions when binding roles to identities to restrict from which locations, agent types, and time frames access can be used. This will provide further flexibility and granularity in least privilege access control.

Diagnostic questions

Google Cloud

Now it's your turn to assess your experience and skills related to this section with some diagnostic questions. Remember, the purpose of these questions is to help you better understand what is involved in this section of the exam guide and identify which areas you'll want to focus on in your study plan.

Please complete the diagnostic questions now

- The diagnostic questions are available in the workbook.

Please take 15 minutes to complete the diagnostic questions for this section.

Review and study planning

Now let's review how to use these diagnostic questions to help you identify what to include in your study plan.

Your study plan:

Configuring access

- 1.1 Managing Cloud Identity
- 1.2 Managing service accounts
- 1.3 Managing authentication
- 1.4 Managing and implementing authorization controls
- 1.5 Defining the resource hierarchy

We'll approach this review by looking at the key areas of this exam section and the questions you just answered about each one. We'll talk about where you can find out more about each area in the learning path for this certification and/or where to find the information in Google Cloud documentation.

As we go through each one, take notes on the specific courses (and modules!), skill badges, and documentation pages you'll want to emphasize in your study plan.

1.1 | Managing Cloud Identity

Considerations include:

- Configuring Google Cloud Directory Sync and implement single sign-on (SSO) with a third-party identity provider
- Managing a super administrator account
- Automating the user lifecycle management process
- Administering user accounts and groups programmatically
- Configuring Workforce Identity Federation

As Professional Cloud Security Engineer, you should be able to design and implement an identity and access management scheme for the Google Cloud resources of an organization. This includes managing users, groups, and group membership, optionally synchronizing and federating to external identity management systems and designing and leveraging an organizational hierarchy for policy and access control.

Question 1 tested your knowledge of the process used to sync external identities to Cloud Identity. Question 2 asked you to create dynamic groups in Cloud Identity.

1.1 Diagnostic Question 01 Discussion

Cymbal Bank has acquired a non-banking financial company (NBFC). This NBFC uses Active Directory as their central directory on an on-premises Windows Server. You have been tasked with migrating all the NBFC users and employee information to Cloud Identity.

What should you do?

- 
- Run Microsoft System Center Configuration Manager (SCCM) on a Compute Engine instance. Leave the channel unencrypted because you are in a secure Google Cloud environment. Deploy Google Cloud Directory Sync on the Compute Engine instance. Connect to the on-premises Windows Server environment from the instance, and migrate users to Cloud Identity.
 - Run Configuration Manager on a Compute Engine instance. Copy the resulting configuration file from this machine onto a new Compute Engine instance to keep the production environment separate from the staging environment. Leave the channel unencrypted because you are in a secure Google Cloud environment. Deploy Google Cloud Directory Sync on this new instance. Connect to the on-premises Windows Server environment from the new instance, and migrate users to Cloud Identity.
 - Use Cloud VPN to connect the on-premises network to your Google Cloud environment. Select an on-premises domain-joined Windows Server. On the domain-joined Windows Server, run Configuration Manager and Google Cloud Directory Sync. Use Cloud VPN's encrypted channel to transfer users from the on-premises Active Directory to Cloud Identity.
 - Select an on-premises domain-joined Windows Server. Run Configuration Manager on the domain-joined Windows Server, and copy the resulting configuration file to a Compute Engine instance. Run Google Cloud Directory Sync on the Compute Engine instance over the internet, and use Cloud VPN to sync users from the on-premises Active Directory to Cloud Identity.

Google Cloud

Feedback:

A. Incorrect. Active Directory uses unencrypted LDAP. When you use a Compute Engine instance, the communication channel must be encrypted even if it is a trusted Google Cloud environment. Use either LDAPS or Cloud VPN.

B. Incorrect. Active Directory uses unencrypted LDAP. When you use a Compute Engine instance, the communication channel must be encrypted. Use either LDAPS or Cloud VPN.

C. Correct! If you are in an on-premises environment, you can access Active Directory using LDAP. Google Cloud Directory Sync to Cloud Identity communication will be over an HTTPS channel using Cloud VPN.

D. Incorrect. Copying configuration files will not give desired results. Google Cloud Directory Sync on a Compute Engine instance would also need this instance to be a part of an on-premises Windows Active Directory server farm.

Content mapping:

 - M2 Securing Access to Google Cloud
- On-demand course: **Managing Security in Google Cloud**
 - M2 Securing Access to Google Cloud

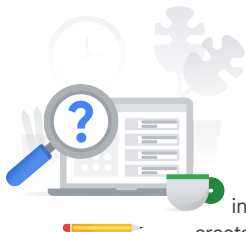

Summary:

Google Cloud Directory Sync deployment requires a secure, isolated environment. Because Active Directory uses LDAP, which is unencrypted, the safest choice is to deploy on-premises. When running Google Cloud Directory Sync remotely or on Google Cloud, ensure that the communication channel is encrypted. You can do this by using Secure LDAP or Cloud VPN. Although this might add a layer of complexity to the process, it ensures that your data transfers are secure. If the source servers support GUI, you can run Configuration Manager to ease the process.

1.1 Diagnostic Question 02 Discussion

Cymbal Bank has certain default permissions and access for their analyst, finance, and teller teams. These teams are organized into groups that have a set of role-based IAM permissions assigned to them. After a recent acquisition of a small bank, you find that the small bank directly assigns permissions to their employees in IAM. You have been tasked with applying Cymbal Bank's resource hierarchy to the small bank. Employees will need access to Google Cloud services.

What should you do?

- 
- A. Leave all user permissions as-is in the small bank's IAM. Use the Directory API in the Google Workspace Admin SDK to create Google Groups. Use a Python script to allocate users to the Google Groups.
 - B. Reset all user permissions in the small bank's IAM. Use Cloud Identity to create dynamic groups for each of the bank's teams. Use the dynamic groups' metadata field for team type to allocate users to their appropriate group with a Python script.
 - C. Reset all user permissions in the small bank's IAM. Use Cloud Identity to create the required Google Groups. Upgrade the Google Groups to Security Groups. Use a Python script to allocate users to the groups.
 - D. Reset all user permissions in the small bank's IAM. Use the Directory API in the Google Workspace Admin SDK to create Google Groups. Use a Python script to allocate users to the groups.

Google Cloud

Feedback:

A. Incorrect. You need to reset permissions in IAM and create Dynamic Groups. Using Google Groups from the Workspace Admin SDK Directory APIs allows access to Google Drive and Docs, but not to Google Cloud resources. Dynamic groups allow you to create and automatically manage users based on identity attributes.

B. Correct! Use Dynamic Groups to create groups based on Identity attributes, such as department, and place the users in a flat hierarchy. Dynamic group metadata helps build the structure to identify the users.

C. Incorrect. Upgrading to Security Groups helps create a protective access layer, but does not fulfill your criterion to apply Cymbal Bank's structure.

D. Incorrect. Using Google Groups from the Workspace Admin SDK Directory APIs allows access to Google Drive and Docs, but not to Google Cloud resources.

Content mapping:

- ILT course: **Security in Google Cloud**
 - M2 Securing Access to Google Cloud

- On-demand course: **Managing Security in Google Cloud**
 - M2 Securing Access to Google Cloud

Summary:

Cloud Identity supports creating groups and then placing users inside those groups. Groups help with managing permissions, access controls, and organizational policies. In Dynamic Groups, users are automatically managed and added based on Identity attributes, such as department.

1.2 | Managing service accounts

Considerations include:

- Securing and protecting service accounts (including default service accounts)
- Identifying scenarios requiring service accounts
- Creating, disabling, and authorizing service accounts
- Securing, auditing and mitigating the usage of service account keys
- Managing and creating short-lived credentials
- Configuring Workload Identity Federation
- Managing service account impersonation

A Professional Cloud Security Engineer should be familiar with Google Cloud service accounts, the key details of their usage and maintenance, and best practices for using them securely.

Question 3 tested your knowledge of applying Google-recommended practices to create and manage service accounts. Question 4 asked you to define service account usage policy based on organizational requirements.

1.2 Diagnostic Question 03 Discussion

Cymbal Bank leverages Google Cloud storage services, an on-premises Apache Spark Cluster, and a web application hosted on a third-party cloud. The Spark cluster and web application require limited access to Cloud Storage buckets and a Cloud SQL instance for only a few hours per day. You have been tasked with sharing credentials while minimizing the risk that the credentials will be compromised.

What should you do?

- 
- A. Create a service account with appropriate permissions. Authenticate the Spark Cluster and the web application as direct requests and share the service account key.
 - B. Create a service account with appropriate permissions. Have the Spark Cluster and the web application authenticate as delegated requests, and share the short-lived service account credential as a JWT.
 - C. Create a service account with appropriate permissions. Authenticate the Spark Cluster and the web application as a delegated request, and share the service account key.
 - D. Create a service account with appropriate permissions. Have the Spark Cluster and the web application authenticate as a direct request, and share the short-lived service account credentials as XML tokens.

Google Cloud

Feedback:

A. Incorrect. Sharing a service account key creates unnecessary exposure, which increases the possibility of spoofing and unauthorized impersonation. This also violates the principle of least privilege.

B. Correct! Delegated requests allow a service account to authenticate into a chain of services. Using short-lived service account credentials provides limited access to trusted services.

C. Incorrect. Although a delegate request is the correct method, sharing a service account key for long durations increases the risk exposure to unauthorized parties.

D. Incorrect. Although short-lived service account credentials are the most secure option, delegated requests instead of direct requests should be used by applications.

 - M4 Securing Google Kubernetes Engine: Techniques and Best Practices
- Skill badge: Implement Cloud Security Fundamentals on Google Cloud

Summary:

Short-lived credentials help a service account share credentials to trusted requests without compromising the access key and similar credentials. Credential types could be self-signed JWT or blobs, OAuth 2.0 access tokens, or OpenID Connect ID Tokens. Delegated requests help a service account authenticate to a chain of services, with limited and separate permissions for each service.

1.2 Diagnostic Question 04 Discussion

Cymbal Bank recently discovered service account key misuse in one of the teams during a security audit. As a precaution, going forward you do not want any team in your organization to generate new external service account keys. You also want to restrict every new service account's usage to its associated Project.

What should you do?

- 
- A. Navigate to Organizational policies in the Google Cloud Console. Select your organization. Select `iam.disableServiceAccountKeyCreation`. Customize the **applied to** property, and set **Enforcement** to 'On'. Click Save. Repeat the process for `iam.disableCrossProjectServiceAccountUsage`.
 - B. Run the `gcloud resource-manager org-policies enable-enforce` command with the constraints `iam.disableServiceAccountKeyCreation`, and `iam.disableCrossProjectServiceAccountUsage` and the Project IDs you want the constraints to apply to.
 - C. Navigate to Organizational policies in the Google Cloud Console. Select your organization. Select `iam.disableServiceAccountKeyCreation`. Under Policy Enforcement, select **Merge with parent**. Click **Save**. Repeat the process for `iam.disableCrossProjectServiceAccountLienRemoval`.
 - D. Run the `gcloud resource-manager org-policies allow` command with the boolean constraints `iam.disableServiceAccountKeyCreation` and `iam.disableCrossProjectServiceAccountUsage` with Organization ID.

Google Cloud

Feedback:

A. Correct! Boolean constraints help you limit service account usage. `iam.disableServiceAccountKeyCreation` will restrict the creation of new external service account keys. `iam.disableCrossProjectServiceAccountUsage` will prevent service accounts from being attached to resources in other projects.

B. Incorrect. You use the `enable-enforce` command with individual boolean constraints. You would also pass the organization ID, not the Project ID, to enforce the constraint.

C. Incorrect. Policy Enforcement and Merge with parent are used to merge list constraints to parent policies. For boolean constraints, first select the constraint, and then under **Applies to**, click **Customize**. Set **Enforcement** to **On**.

D. Incorrect. The command `org-policies allow` is used to consume list constraints, not boolean constraints. Run the command to select boolean constraints individually with the Organization ID.

Summary:

Service account usage policies can expose or limit the actions that service accounts can take. At an organization level, it is important to limit the service account activities because service accounts are prone to impersonation. Sharing between projects and exposing their keys for a long time can compromise the key.

1.3 | Managing authentication

Considerations include:

- Creating a password and session management policy for user accounts
- Setting up Security Assertion Markup Language (SAML) and OAuth
- Configuring and enforcing two-step verification

As a Professional Cloud Security Engineer, you should be able to define the authentication process for an organization based on requirements. You should be familiar with federated identity authentication and single-sign on with SAML and the benefits and details of configuration for enforcing two step verification.

Question 5 tested your ability to enable SSO for Google Cloud using SAML configuration. Question 6 tested your knowledge of the steps to create custom IAM roles.

1.3 Diagnostic Question 05 Discussion

Cymbal Bank publishes its APIs through Apigee. Cymbal Bank has recently acquired ABC Corp, which uses a third-party identity provider. You have been tasked with connecting ABC Corp's identity provider to Apigee for single sign-on (SSO). You need to set up SSO so that Google is the service provider. You also want to monitor and log high-risk activities. Which two choices would you select to enable SSO?

Which two choices would you select to enable SSO?

- 
- A. Use openssl to generate public and private keys. Store the public key in an X.509 certificate, and encrypt using RSA or DSA for SAML. Sign in to the Google Admin console, and under **Security**, upload the certificate.
 - B. Use openssl to generate a private key. Store the private key in an X.509 certificate, and encrypt using AES or DES for SAML. Sign in to the Google Workspace Admin Console and upload the certificate.
 - C. Use openssl to generate public and private keys. Store the private key in an X.509 certificate, and encrypt using AES or DES for SAML. Sign in to the Google Admin console, and under Security, upload the certificate.
 - D. Review Network mapping results, and assign SSO profiles to required users.
 - E. Review Network mapping results, and assign SAML profiles to required users.

Google Cloud

Feedback:

A. Correct! The first step is to generate a set of public and private keys. The public key is then stored in an X.509 certificate encrypted with RSA or DSA. Navigate to the Google Admin console to upload the certificate. The generated private key will be used to sign the SAML messages and responses.

B. Incorrect. AES and DES are symmetric encryptions and generate only private keys. You need an asymmetric encryption to generate two keys: public and private. To upload the certificate, you need to use the Google Admin console, not the Google Workspace Admin Console.

C. Incorrect. AES and DES are symmetric encryptions and generate only private keys. You need an asymmetric encryption to generate two keys: public and private. The public key will be stored in an X.509 certificate. The private key will be used to sign the SAML messages and responses. However, using the Google Admin console to upload the certificate is the right choice.

D. Correct! Network maps and masks control the allocated IP address ranges and redirections.

E. Incorrect. An SSO profile must be assigned to the selected users. SAML profiles are assertions and policies to enable SSO profiles.

Summary:

SAML allows third-party identity services to enable single sign-on to Google platforms (Google being the service provider). Apigee uses SAML to enable single sign-on capabilities that are managed through the Google Admin console and require you to generate encrypted X.509 certificates storing public keys.

1.3 Diagnostic Question 06 Discussion

You are an administrator for Cymbal Bank's Mobile Development Team. You want to control how long different users can access the Google Cloud console, the Cloud SDK, and any applications that require user authorization for Google Cloud scopes without having to reauthenticate. More specifically, you want users with elevated privileges (project owners and billing administrators) to reauthenticate more frequently than regular users at the organization level.

What should you do?

- A. Open all Google Cloud projects that belong to Cymbal Bank's Mobile Development team. Find each project's Google Cloud session control setting, and configure a reauthentication policy that requires reauthentication. Choose the reauthentication frequency from the drop-down list.
- B. In the Admin console, select Google Cloud session control and set a reauthentication policy that requires reauthentication. Choose the reauthentication frequency from the drop-down list.
- C. Create a custom role for project owners and billing administrators at the organization level in the Google Cloud console. Add the `reauthenticationRequired` permission to this role. Assign this role to each project owner and billing administrator.
- D. Create a custom role for project owners and billing administrators at the organization level in the Google Cloud console. Add the `reauthenticationRequired` permission to this role. Create a Google Group that contains all billing administrators and project owners. Apply the custom role to the group.

Google Cloud

Feedback:

A. Incorrect. Reauthentication policies are configured in the Admin console. The question also asks to configure this at the organization, not project level.

B. Correct! Session control settings are configured in the Admin console. These settings will be set at the organization level and will include all project owners and billing administrators in the organization.

C. Incorrect. The `reauthenticationRequired` permissions do not exist. Your set reauthentication policies are configured in the Admin console.

D. Incorrect. While applying roles to Google Groups is a best practice, the `reauthenticationRequired` permission does not exist. Your set reauthentication policies are configured in the Admin console.

Where to look:

- <https://support.google.com/a/answer/9368756?hl=en>

Summary:

As an administrator, you can control how long different users can access the Google Cloud console and Cloud SDK without having to reauthenticate. For example, you might want users with elevated privileges, like project owners, billing administrators, or others with administrator roles, to reauthenticate more frequently than regular users. If you set a session length, they're prompted to sign in again to start a new

session.

The session length setting applies to:

- The Google Cloud console
- The gcloud command-line tool (Cloud SDK)
- Any applications (including third-party applications, or your own applications) that require user authorization for Google Cloud scopes. To review the apps requiring Google Cloud scopes in the Apps access control UI, see [Control which third-party & internal apps access Google Workspace data](#).

1.4 Managing and implementing authorization controls

Considerations include:

- Managing privileged roles and separation of duties with Identity and Access Management (IAM) roles and permissions
- Managing IAM and access control list (ACL) permissions
- Granting permissions to different types of identities, including using IAM conditions and IAM deny policies
- Defining access control at the organization, folder, project, and resource level using the principle of least privilege
- Configuring Access Context Manager
- Applying Policy Intelligence
- Managing permissions through groups
- Identifying use cases and configuring Privileged Access Manager

Google Cloud

A Professional Cloud Security Engineer should be familiar with the authorization model of Google Cloud. You should be familiar with the Google Cloud concept of members (or identities or principals), roles, and permissions. You should be able to leverage basic, predefined, and custom roles bound to identities at various levels of the organization hierarchy to enforce least privilege access and separation of duties. Additionally, you should understand supplementary access control capabilities such as access levels in the Access Context Manager, and just-in-time, time-bound, and approval-based access elevations using Privileged Access Manager.

Question 7 tested your understanding of using roles at different levels of an organizational hierarchy. Question 8 asked you to select basic, predefined, or custom IAM roles for a specific scenario.

1.4 Diagnostic Question 07 Discussion

Cymbal Bank's organizational hierarchy divides the Organization into departments. The Engineering Department has a 'product team' folder. This folder contains folders for each of the bank's products. Each product folder contains one Google Cloud Project, but more may be added. Each project contains an App Engine deployment.

Cymbal Bank has hired a new technical product manager and a new web developer. The technical product manager must be able to interact with and manage all services in projects that roll up to the Engineering Department folder. The web developer needs read-only access to App Engine configurations and settings for a specific product.

How should you provision the new employees' roles into your hierarchy following principles of least privilege?

- A. Assign the Project Editor role in each individual project to the technical product manager. Assign the Project Editor role in each individual project to the web developer.
- B. Assign the Project Owner role in each individual project to the technical product manager. Assign the App Engine Deployer role in each individual project to the web developer.
- C. Assign the Project Editor role at the Engineering Department folder level to the technical product manager. Assign the App Engine Deployer role at the specific product's folder level to the web developer.
- D. Assign the Project Editor role at the Engineering Department folder level to the technical product manager. Create a Custom Role in the product folder that the web developer needs access to. Add the `appengine.versions.create` and `appengine.versions.delete` permissions to that role, and assign it to the web developer.

Google Cloud

Feedback:

A. Incorrect. Binding the technical product manager on each project separately will provide the required access, but is not the most efficient approach. This also doesn't address the possibility of new folders (and new projects) that can be added in the future. Providing the web developer with Editor access on the required Project will allow them unnecessary access to other Google Cloud services.

B. Incorrect. Assigning Owner roles in all projects to the technical product manager will provide them with more access than necessary. The web developer should be assigned the predefined 'App Engine Deployer' role, but only for the appropriate folder.

C. Correct! Because the technical product manager must be able to work with services across all projects, you should provide permissions at the Department folder level. The web developer should only be able to administer App Engine deployments in their product folder.

D. Incorrect. Although the correct permissions are assigned to the technical product manager, the web developer is provided permissions that are overly permissive. Custom roles are also not required because the App Engine Deployer role gives the web developer all the required permissions.

Summary:

Folders help create layers of hierarchy and access control between Organization and Projects. Use Folders to create an inheritance of roles and permissions. Provide access at the Project level when the target role needs to work with limited resources. Provide access at the Folder level when the target role needs to work with multiple roles, permissions, and projects.

1.4 Diagnostic Question 08 Discussion

Cymbal Bank's organizational hierarchy divides the Organization into departments. The Engineering Department has a 'product team' folder. This folder contains folders for each of the bank's products. One folder titled "analytics" contains a Google Cloud Project that contains an App Engine deployment and a Cloud SQL instance.

A team needs specific access to this project. The team lead needs full administrative access to App Engine and Cloud SQL. A developer must be able to configure and manage all aspects of App Engine deployments. There is also a code reviewer who may periodically review the deployed App Engine source code without making any changes.

What types of permissions would you provide to each of these users?

- A. Create custom roles for all three user types at the "analytics" folder level. For the team lead, provide all `appengine.*` and `cloudsql.*` permissions. For the developer, provide `appengine.applications.*` and `appengine.instances.*` permissions. For the code reviewer, provide the `appengine.instances.*` permissions.
- B. Assign the basic 'App Engine Admin' and 'Cloud SQL Admin' roles to the team lead. Assign the 'App Engine Admin' role to the developer. Assign the 'App Engine Code Viewer' role to the code reviewer. Assign all these permissions at the analytics project level.
- C. Create custom roles for all three user types at the project level. For the team lead, provide all `appengine.*` and `cloudsql.*` permissions. For the developer, provide `appengine.applications.*` and `appengine.instances.*` permissions. For the code reviewer, provide the `appengine.instances.*` permissions.
- D. Assign the basic 'Editor' role to the team lead. Create a custom role for the developer. Provide all `appengine.*` permissions to the developer. Provide the predefined 'App Engine Code Viewer' role to the code reviewer. Assign all these permissions at the "analytics" folder level.

Google Cloud

Feedback:

A. Incorrect. Custom roles are not required in this scenario. The team lead, developer, and code reviewer can all be assigned predefined roles to match their job functions. Permissions also need to be set at the project, not folder, level.

B. Correct! The team lead needs full access to the App Engine and Cloud SQL services. The developer needs to administer App Engine deployments. The 'App Engine Code Viewer' role allows the code reviewer to access deployed source code.

C. Incorrect. Although the permissions are set at the project level, there is no requirement for custom roles. Also, the developer would need more than `appengine.applications.*` and `appengine.instances.*` for full administrative access to the tool.

D. Incorrect. The basic 'Editor' role is too coarse-grained for the team lead. The Developer needs the predefined role of 'App Engine Admin'. You can assign the 'App Engine Code Viewer' for the code reviewer; a custom role is not required. Permissions also need to be set at the project, not folder, level.

Summary:

IAM roles are of 3 types: basic, predefined, and custom. Basic roles of 'Owner,' 'Editor,' and 'Viewer' provide a large set of broad permissions that existed before IAM. Most often, basic roles are not recommended because of the large number of permissions they contain. Predefined roles limit the permissions and access that a role has and are defined separately for each Google Cloud resource. Create custom roles when the predefined roles provide more permission than required.

1.5 | Defining the resource hierarchy

Considerations include:

- Managing folders and projects at scale
- Managing pre-built or custom organization policies for the organization, folders, and projects
- Using the resource hierarchy for access control and permissions inheritance

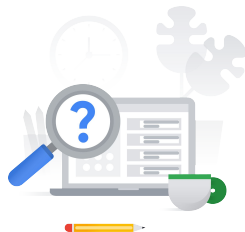

As a Professional Cloud Security Engineer, you are expected to help design and implement the organizational hierarchy. You will leverage this hierarchy to set trust and security boundaries via access control and organizational policy constraints bound at various levels of the hierarchy.

Question 9 asked you to create a resource hierarchy that aligns with a given organizational structure and access control requirements. Question 10 tested your knowledge of designing a hierarchy and policies to control access to Google Cloud resources.

1.5 Diagnostic Question 09 Discussion

Cymbal Bank is divided into separate departments. Each department is divided into teams. Each team works on a distinct product that requires Google Cloud resources for development.

How would you design a Google Cloud organization hierarchy to best match Cymbal Bank's organization structure and needs?

- 
- A. Create an Organization node. Under the Organization node, create Department folders. Under each Department, create Product folders. Under each Product, create Teams folders. In the Teams folder, add Projects.
 - B. Create an Organization node. Under the Organization node, create Department folders. Under each Department, create Product folders. Add Projects to the Product folders.
 - C. Create an Organization node. Under the Organization node, create Department folders. Under each Department, create Teams folders. Add Projects to the Teams folders.
 - D. Create an Organization node. Under the Organization node, create Department folders. Under each Department, create a Teams folder. Under each Team, create Product folders. Add Projects to the Product folders.

Google Cloud

Feedback:

A. Incorrect. This hierarchy would place Teams under Product. Teams should be above products.

B. Incorrect. This hierarchy is missing the Teams layer.

C. Incorrect. Creating Projects directly inside Teams would make it difficult to distinguish teams and their roles in different Projects. Teams should have Product folders with Projects inside them.

D. Correct! Departments have teams, which work on products. This hierarchy best fits Cymbal Bank's organization structure.

Content mapping:

Summary:

Organization hierarchy helps build an inheritance of policies and permissions. Although Projects can be placed directly in an Organization, creating layers of folders in between helps with managing different permissions for different access. You can also use folders to derive an inheritance of policies and permissions.

1.5 Diagnostic Question 10 Discussion

Cymbal Bank has a team of developers and administrators working on different sets of Google Cloud resources. The Bank's administrators should be able to access the serial ports on Compute Engine Instances and create service accounts. Developers should only be able to access serial ports.

How would you design the organization hierarchy to provide the required access?

- A. Deny Serial Port Access and Service Account Creation at the Organization level. Create an 'admin' folder and set enforced: false for constraints/compute.disableSerialPortAccess. Create a new 'dev' folder inside the 'admin' folder, and set enforced: false for constraints/iam.disableServiceAccountCreation. Give developers access to the 'dev' folder, and administrators access to the 'admin' folder.
- B. Deny Serial Port Access and Service Account Creation at the organization level. Create a 'dev' folder and set enforced: false for constraints/compute.disableSerialPortAccess. Create a new 'admin' folder inside the 'dev' folder, and set enforced: false for constraints/iam.disableServiceAccountCreation. Give developers access to the 'dev' folder, and administrators access to the 'admin' folder.
- C. Deny Serial Port Access and Service Account Creation at the organization level. Create a 'dev' folder and set enforced: true for constraints/compute.disableSerialPortAccess and enforced: true for constraints/iam.disableServiceAccountCreation. Create a new 'admin' folder inside the 'dev' folder, and set enforced: false for constraints/iam.disableServiceAccountCreation. Give developers access to the 'dev' folder, and administrators access to the 'admin' folder.
- D. Allow Serial Port Access and Service Account Creation at the organization level. Create a 'dev' folder and set enforced: true for constraints/iam.disableServiceAccountCreation. Create another 'admin' folder that inherits from the parent inside the organization node. Give developers access to the 'dev' folder, and administrators access to the 'admin' folder.

Google Cloud

Feedback:

A. Incorrect. Although this hierarchy allows serial port access in the 'admin' folder, it will not allow Admins to create service accounts. This hierarchy incorrectly lets Developers create service accounts.

B. Correct! These organizational constraints will prevent all users from accessing serial ports on Compute Engine instances and creating service accounts. You can override these constraints in a new folder by setting the common constraint for serial port access. Creating another folder inside a parent folder will allow you to inherit the constraint and will allow you to add additional constraints to create a service account. Admins and developers are added appropriately.

C. Incorrect. This hierarchy disables serial port access for developers and service account creation for admins. Hierarchies should be defined cleanly and with the fewest contradictions to avoid confusion.

D. Incorrect. Allowing Serial Port Access and Service Account Creation at the organization level defeats the problem statement, which specifies that only the bank's Administrators should be able to access the serial ports on Compute Engine Instances and create service accounts. You should 'DENY' the permissions at the organization level and enable them at the folder or Project level.
