# Session logistics

## Questions

In Google Meet, click the raise hand button or add your question to the Q&A section.

Answers may be deferred until the end of the session.

## Slide availability

These slides are available in the Student Lecture section of your Qwiklabs classroom.

## Recording

The session is **not** recorded.

## Chat

As Google Meet does not have persistent chat, you will lose chat history if you get disconnected. Save URLs as they appear.

Google Cloud

When you have a question, please:

Click the Raise hand button in Google Meet.

Or add your question to the Q&A section of Google Meet.

Please note that answers may be deferred until the end of the session.

These slides are available in the Student Lecture section of your Qwiklabs classroom.

The session is not recorded.

Google Meet does not have persistent chat.

If you get disconnected, you will lose the chat history.

Please copy any important URLs to a local text file as they appear in the chat.

# Today's agenda

- 01** Advanced Logging and Analysis
- 02** Monitoring Network Security and Audit Logs
- 03** Network Architecture Design Approach
- 04** Designing the VPC Architecture for the Workloads
- 05** Designing the Hybrid Connectivity
- 06** Hybrid Connectivity to a Single VPC (for Shared VPC)

# Objectives

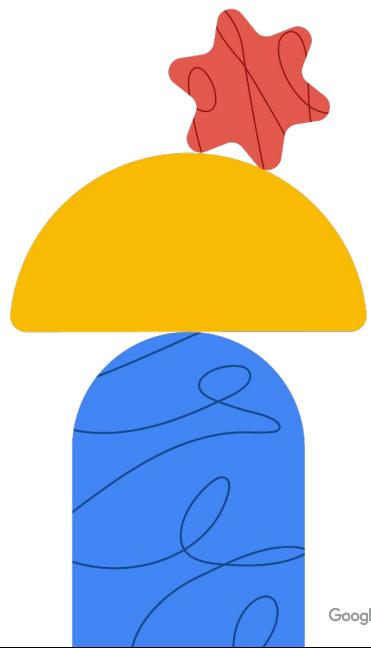

- 01 Explain network-related monitoring.
- 02 Explain network-related logging.
- 03 Describe network design approach.

Google Cloud

## AGENDA

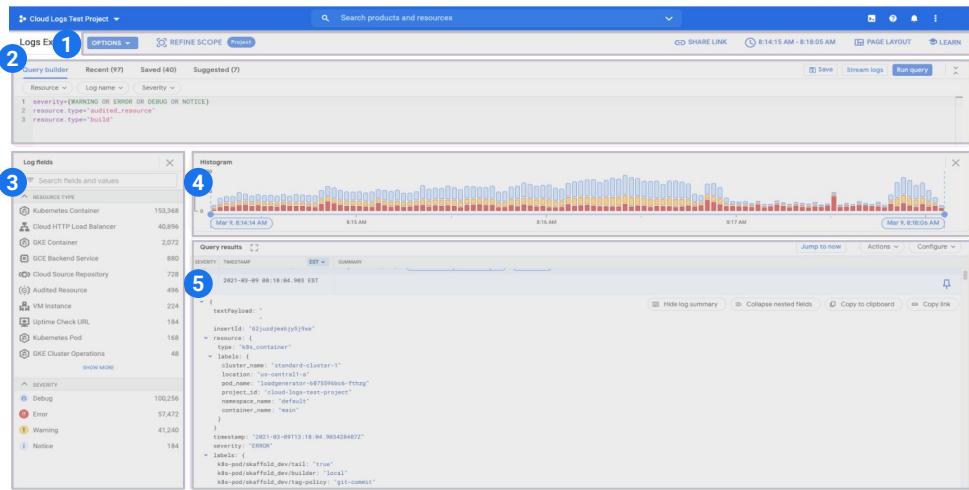

# Advanced Logging and Analysis

Google Cloud

In this module, you'll examine some of Google Cloud's advanced logging and analysis capabilities.

# Logs Explorer interface

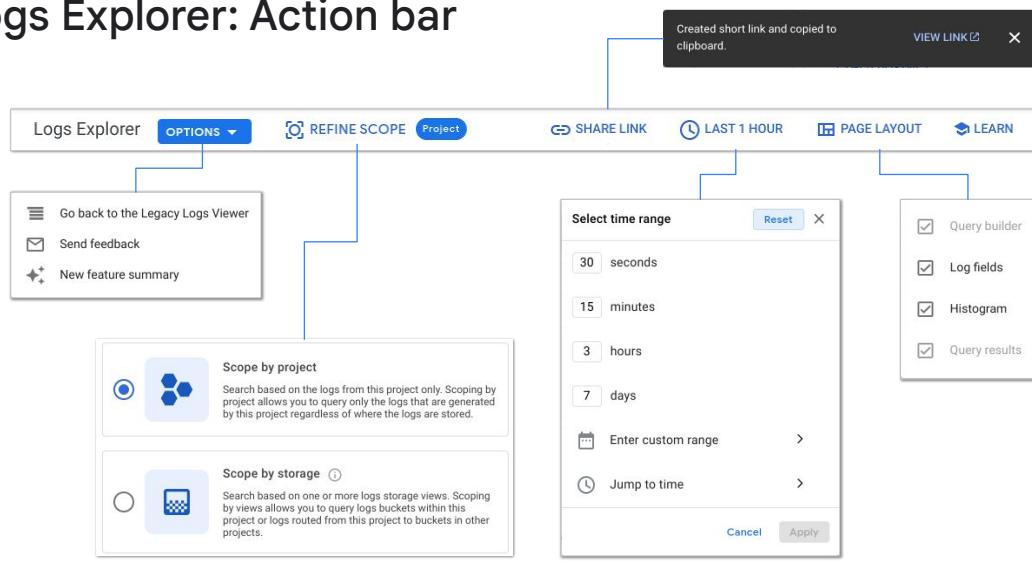

Google Cloud

The Logs Explorer interface lets you retrieve logs, parse and analyze log data, and refine your query parameters. The Logs Explorer contains the following panes:

1. Action bar
2. Query builder
3. Log fields
4. Histogram
5. Query results

# Logs Explorer: Action bar

Google Cloud

From the **Action bar** pane, you can access the following:

1. **Options:** Lets you go to the Legacy Logs Viewer, send feedback, and view a summary of new Logging features.
2. **Refine scope:** Lets you scope your search by logs in your current Cloud project only or by one or more storage views. For more information, see [Refining scope](#).
3. **Share link:** Lets you create a shortened URL of the current query and copies it to your clipboard, making it easier to share a query.
4. **Time-range selector:** Lets you restrict query results by time range. The default time range is one hour.
5. **Page layout:** Lets you enable and disable the **Histogram** and **Logs field explorer** panes.
6. **Learn:** Lets you view links to relevant documentation.

# Logs Explorer: Query builder

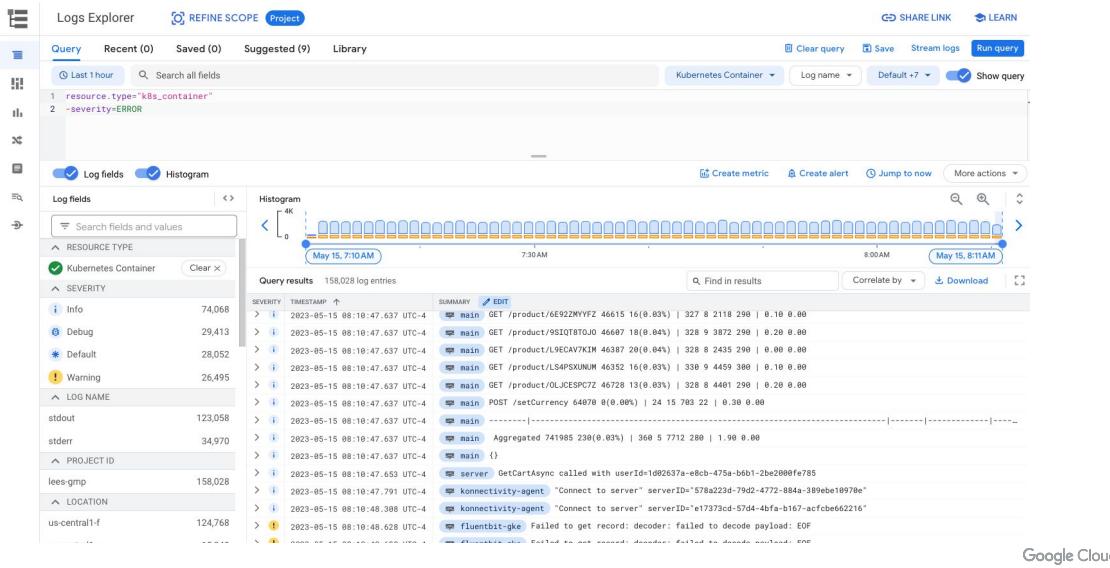

Google Cloud

From the **Query builder** pane, you can access the following:

1. **Query-builder field:** Lets you build queries using the [Logging query language](#).
2. **Query builder drop-down menus:** Lets you add query expressions based on **Resource**, **Log name**, and **Severity**. For more information, see [Query builder drop-down menus](#).
3. **Recent:** Lets you view your recent queries. For more information, see [Recent queries](#).
4. **Saved:** Lets you view your saved queries and queries that other users of the Cloud project have shared with you. For more information, see [Saved queries](#) and [Shared queries](#).
5. **Suggested:** Lets you view suggested queries based on the resources in your Cloud project. For more information, see [Suggested queries](#).
6. **Save:** Lets you save queries that can be viewed and run from the **Saved** tab.
7. **Stream logs:** Lets you view log entries as Logging ingests them. For more information, see [Streaming logs](#).
8. **Run query:** Lets you run your queries after you have built them in the query-builder field.

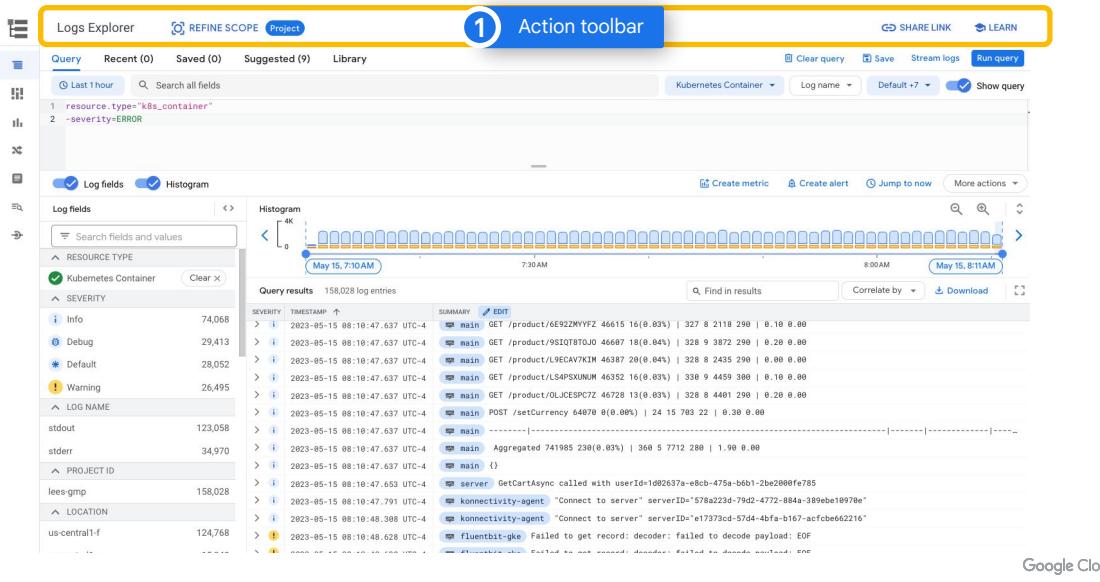

# Logs Explorer: Query results

Google Cloud

The Logs Explorer interface lets you retrieve logs, parse and analyze log data, and refine your query parameters. The Logs Explorer contains the following panes:

# Logs Explorer: Query results

- Action toolbar:** Action toolbar to refine logs to projects or storage views, share a link and learn about logs explorer.

# Logs Explorer: Query results

The screenshot shows the Google Cloud Logs Explorer interface. At the top, there's a navigation bar with 'Logs Explorer', 'REFINE SCOPE', and 'Project' tabs. Below the navigation bar is the 'Action toolbar' (labeled 1) containing buttons for 'SHARE LINK', 'LEARN', 'Clear query', 'Save', 'Stream logs', and 'Run query'. To the right of the toolbar is the 'Query pane' (labeled 2), which includes a search bar ('Search all fields') and a query editor with the following log filter:

```
1 resource.type="k8s_container"
2 -severity=ERROR
```

Below the search bar are two checkboxes: 'Log fields' and 'Histogram'. The 'Log fields' section contains a search field ('Search fields and values') and a tree view of log fields categorized by 'RESOURCE TYPE', 'Kubernetes Container', 'SEVERITY', 'LOG NAME', 'PROJECT ID', and 'LOCATION'. The 'Histogram' section shows a timeline from May 15, 7:10 AM to 8:00 AM, with a count of 158,028 log entries. The 'Query results' section displays a list of log entries with columns for 'SEVERITY', 'TIMESTAMP', and 'LOG'. The first few entries are:

SEVERITY	TIMESTAMP	LOG
Info	2023-05-15 08:10:47.637 UTC-4	> [main] GET /product/6E92ZMVFZ 46615 16(0.03%)   327 8 2118 290   0.10 0.00

Warning	2023-05-15 08:10:48.628 UTC-4	> [fluentbit-gke] Failed to read record: decoder: failed to decode payload: EOF

At the bottom right of the interface is the 'Google Cloud' logo.

2. **Query pane:** Query pane is where you can build queries, view recently viewed and saved queries and a lot more.

## Logs Explorer: Query results

The screenshot shows the Google Cloud Logs Explorer interface. At the top, there's a navigation bar with 'Logs Explorer', 'REFINE SCOPE', and 'Project'. Below it is the 'Action toolbar' (1) with buttons for 'SHARE LINK' and 'LEARN'. The 'Query pane' (2) contains a search bar and a query editor with the following log filter:

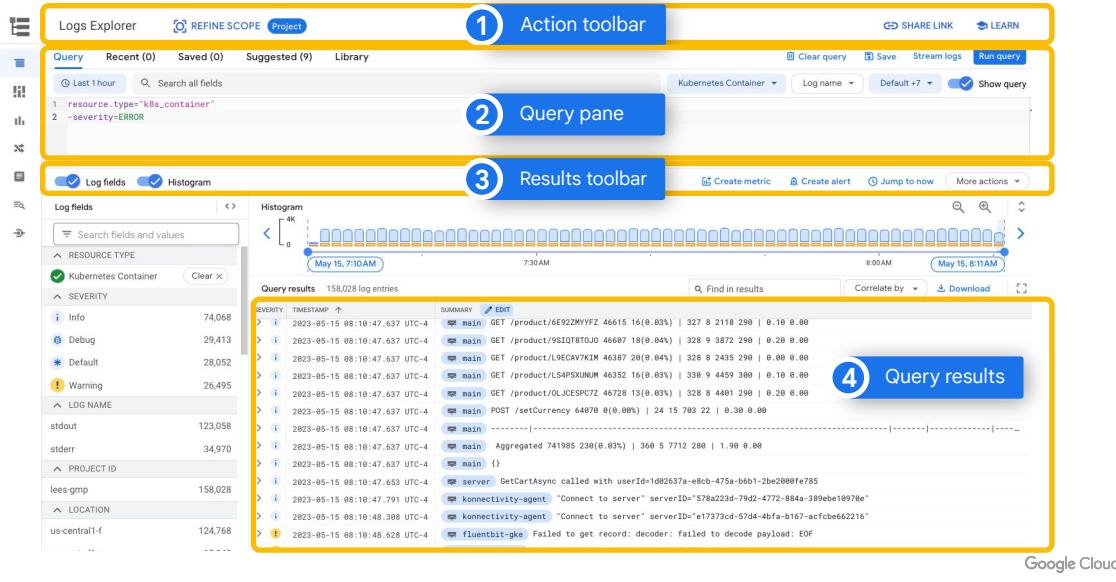

```
1 resource.type="k8s_container"
2 -severity:ERROR
```

The 'Results toolbar' (3) includes options for 'Create metric', 'Create alert', 'Jump to now', and 'More actions'. On the left, the 'Log fields' sidebar shows metrics like 'Kubernetes Container' (74,068), 'Severity' (Info: 74,068, Debug: 29,413, Default: 28,052, Warning: 26,495), and 'LOG NAME' (stdout: 123,058, stderr: 34,970). The main area displays a histogram and a list of 'Query results' (158,028 log entries) with columns for 'SEVERITY', 'TIMESTAMP', and 'LOG'. A summary table at the bottom provides detailed statistics for each severity level.

Google Cloud

3. **Results Toolbar:** This can be used to quickly show or hide logs and histogram pane nad create a log based metric or alert. **Jump to now** option helps query and view the current time results.

## Logs Explorer: Query results

4. **Query results:** Is the details of results with a summary and timestamp that helps troubleshoot further.

# Logs Explorer: Query results

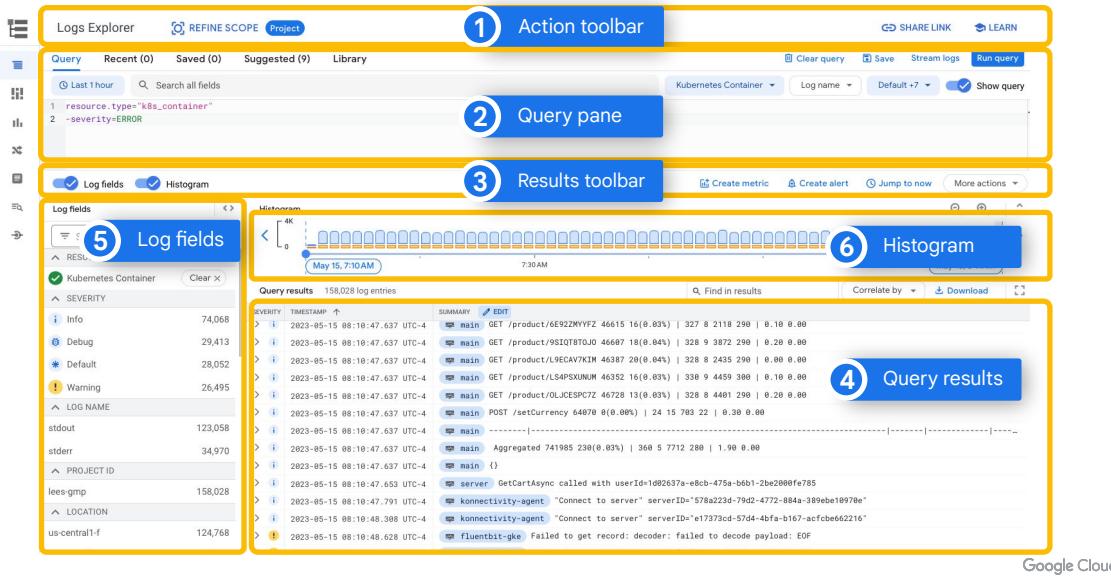

The screenshot shows the Google Cloud Logs Explorer interface with several components highlighted:

- Action toolbar**: Located at the top, it includes a search bar, a query editor with filters like "resource.type=k8s\_container" and "-severity=ERROR", and buttons for "SHARE LINK", "LEARN", "Clear query", "Save", "Stream logs", and "Run query".
- Query pane**: Below the toolbar, it displays the current query and its results.
- Results toolbar**: Contains options for "Create metric", "Create alert", "Jump to now", and "More actions".
- Log fields pane**: On the left, labeled with a blue circle containing the number 5, it lists log fields categorized by severity (Info, Debug, Default, Warning) and log name (stdout, stderr, PROJECT ID, LOCATION). It also shows resource counts like 74,068 for Info and 123,058 for stdout.
- Query results**: The main pane on the right shows a histogram of log entries over time (May 15, 7:10 AM to 8:00 AM) and a detailed list of 158,028 log entries. The results table has columns for SEVERITY, TIMESTAMP, and SUMMARY. Some entries include details like method, URL, and status code.

Google Cloud

5. **Log fields**: Log fields pane is used to filter your options based on various factors such as a resource type, log name, project ID, etc.,

# Logs Explorer: Query results

Google Cloud

6. **Histogram:** Histogram is where the query result is visualized a histogram bars, where each bar is a time range and is color coded based on severity.

# Entries are returned as LogEntry objects

The screenshot shows a single log entry in the Google Cloud Logs Explorer. The log entry is a JSON object representing a `protoPayload` from a `google.cloud.audit.AuditLog`. The entry details a `google.cloud.run.v1.Services.CreateService` request made by `patrick.haggerty@roitraining.com` to `run.googleapis.com` at `2020-09-16 11:49:38.815 CDT`. The request was successful (`status:ok`) and was made from IP `72.24.18.24` using Mozilla/5.0 (Macintosh; Intel Mac OS X 10\_15\_6) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/85.0.4183.102 Safari/537.36. The user agent information also includes `gzip(gfe),gzip(gfe)`. The log also contains `requestMetadata`, `resourceName`, `methodName`, and `authorizationInfo` fields.

```

{
  "protoPayload": {
    "@type": "type.googleapis.com/google.cloud.audit.AuditLog",
    "authenticationInfo": {
      "principalEmail": "patrick.haggerty@roitraining.com"
    },
    "requestMetadata": {
      "callerIp": "72.24.18.24",
      "callerSuppliedUserAgent": "Mozilla/5.0 (Macintosh; Intel Mac OS X 10_15_6) AppleWebKit/537.36 (KHTML, like Gecko) Chrome/85.0.4183.102 Safari/537.36,gzip(gfe),gzip(gfe)"
    },
    "resourceAttributes": {
      "time": "2020-09-16T11:49:39.035111Z",
      "auth": {}
    },
    "destinationAttributes": {}
  },
  "resourceName": "run.googleapis.com",
  "methodName": "google.cloud.run.v1.Services.CreateService",
  "authorizationInfo": [
    {
      "B": {
        "resource": "namespaces/vellossandbox/services/demo",
        "permission": "run.services.create",
        "granted": true,
        "resourceAttributes": {}
      }
    }
  ],
  "request": {
    "service": {
      "apiVersion": "serving.knative.dev/v1"
    },
    "kind": "Service"
  }
}

```

Google Cloud

The entries returned in Logs Explorer are based on Google's [LogEntry](#) datatype. They contain data like the `logName`, `severity`, `resource.type`, and various payload fields.

## Primary log fields

Field name	Description
logName	Resource name of the log to which this log entry belongs (ex: projects/[PROJECT_ID]/logs/[LOG_ID] )
insertId	Unique identifier
severity	Entry severity, defaults to LogSeverity.DEFAULT
timestamp/receiveTimestamp	The time the event described by the log entry occurred/was received by Logging
resource.type	The name of a resource type. Example: gce_instance
resource.labels.KEY	The value associated with a resource label key
httpRequest.FIELD	The value of a field in an HttpRequest object (method, url, size, status, etc.)
labels.KEY	The value associated with a label key
operation.FIELD	The value of a field in a LogEntryOperation object
protoPayload.FIELD	Log entry payload represented as a protocol buffer
jsonPayload.FIELD	The value of a field within a JSON object
textPayload	The log entry payload, represented as a Unicode string (UTF-8)

Google Cloud

Here you see common What is displayed now is common LogEntry properties. Note that *textPayload*, *jsonPayload*, and *protoPayload* are mutually exclusive. Also, the information that is typically most interesting and/or most relevant will be found in the provided payload section.

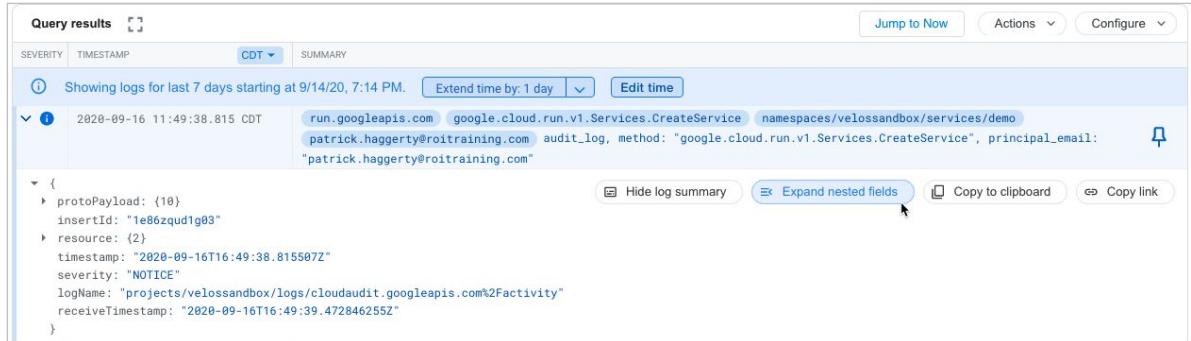

# Log entries

Query results				
SEVERITY	TIMESTAMP	CDT	SUMMARY	
INFO	Showing logs for last 7 days starting at 9/14/20, 7:14 PM.	<a href="#">Extend time by 1 day</a>	<a href="#">Edit time</a>	
> INFO	2020-09-16 11:49:38.815 CDT	run.googleapis.com	google.cloud.run.v1.Services.CreateService namespaces/velossandbox/services/demo -	
> INFO	2020-09-16 11:49:39.110 CDT	run.googleapis.com	google.cloud.run.v1.Services.SetIamPolicy projects/velossandbox/locations/us-central1/services/demo -	
> INFO	2020-09-19 17:51:15.318 CDT	run.googleapis.com	google.cloud.run.v1.Services.DeleteService namespaces/velossandbox/services/demo -	
> INFO	2020-09-21 12:54:14.061 CDT	servicemanagement.googleapis.com	google.api.servicemanagement.v1.ServiceManager.ActivateServices -	
> INFO	2020-09-21 12:54:16.868 CDT	servicemanagement.googleapis.com	google.api.servicemanagement.v1.ServiceManager.ActivateServices -	
INFO	Showing logs for last 7 days ending at 9/21/20, 7:14 PM.	<a href="#">Extend time by 1 day</a>	<a href="#">Edit time</a>	

Google Cloud

The log-entry table displays an entry line for each log entry. In the line, you see the entry severity, timestamp, and any values for fields that have been promoted to the summary.

## Log entry details

The screenshot shows the Google Cloud Logging interface. At the top, there are tabs for 'Query results' (selected), 'SEVERITY', 'TIMESTAMP', and 'CDT'. Below the tabs, it says 'Showing logs for last 7 days starting at 9/14/20, 7:14 PM.' with buttons for 'Extend time by: 1 day' and 'Edit time'. On the right, there are buttons for 'Jump to Now', 'Actions', and 'Configure'. The main area displays a single log entry. The log entry has a timestamp of '2020-09-16 11:49:38.815 CDT' and a severity of 'NOTICE'. It includes fields for 'protoPayload' (containing nested fields like 'insertId', 'resource', 'timestamp', 'severity', 'logName', and 'receiveTimestamp'), 'run.googleapis.com', 'google.cloud.run.v1.Services.CreateService', 'namespaces/velossandbox/services/demo', 'patrick.haggerty@roitraining.com', 'audit\_log', 'method: "google.cloud.run.v1.Services.CreateService"', and 'principal\_email: "patrick.haggerty@roitraining.com"'. There are also buttons for 'Hide log summary', 'Expand nested fields' (which is being clicked), 'Copy to clipboard', and 'Copy link'. A small bell icon is also present.

Google Cloud

To view the full details for one log entry, click the expander arrow (►) at the front of the summary line, and then click **Expand nested fields**. The log entry is displayed using JSON format.

## Locate (or hide) similar entries

```
serviceName: "run.googleapis.com"
methodName: "google.cloud.run.v1.Services.CreateService"
  ↴ authorization
    ↴ 0: {
      ↴ resource: "x/services/demo"
      ↴ permission: "cloud/run.create"
      ↴ granted: true
      ↴ resourceArn: "arn:aws:lambda:us-east-1:123456789012:function:my-function"
    }
  ]
resourceName: "namespaces/velossandbox/services/demo"
```

Google Cloud

You can click the value of a specific field in the expanded log entry view and then either show or hide all log entries with the same value. Doing so will modify the log query appropriately.

## Ultimately, it's the query that selects the entries

- Start with what you know about the entry you're trying to find.
- If it belongs to a resource, a particular log file, or has a known severity, use the query builder drop-down menus.

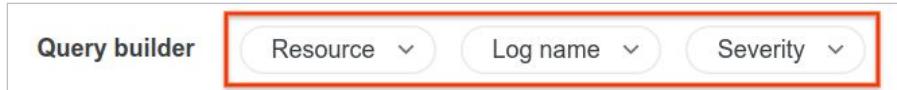

Google Cloud

Ultimately, it's the query that selects the entries displayed by Logs Explorer. Queries may be created directly with the Logging Query Language (LQL), using the drop-down menus, the logs field explorer, or by clicking fields in the results themselves.

Start with what you know about the entry you're trying to find. If it belongs to a resource, a particular log file, or has a known severity, use the query builder drop-down menus.

## Using the query builder drop-down menu

Google Cloud

The query builder drop-down menu makes it easy to start narrowing your log choices.

- **Resource:** Lets you specify `resource.type`. You can select a single resource at a time to add to the **Query builder**. Entries use the logical operator AND.
- **Log name:** Lets you specify `logName`. You can select multiple log names at once to add to the **Query builder**. When selecting multiple entries, the logical operator OR is used.
- **Severity:** Lets you specify `severity`. You can select multiple severity levels at once to add to the **Query builder**. When selecting multiple entries, the logical operator OR is used.

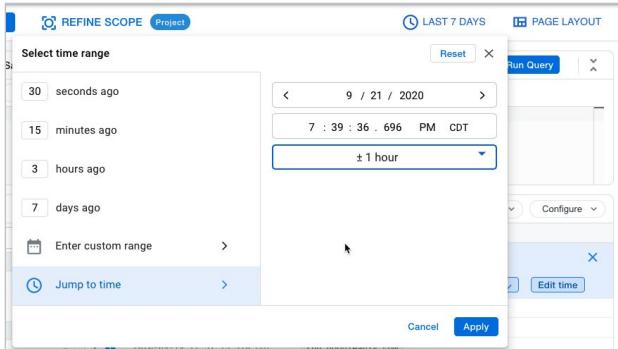

## Advanced filter comparison operators

= Equals	resource.type="gce_instance"
!= Does not equal	resource.labels.instance_id!="1234567890"
<= Less than equal	timestamp <= "2018-08-13T20:00:00Z"
>= More than equal	timestamp >= "2018-08-13T20:00:00Z"
> More than	timestamp > "2018-08-13T20:00:00Z"
< Less than	timestamp < "2018-08-13T20:00:00Z"
: Has	textPayload:"GET /check"

Google Cloud

The next several slides are included for reference. Advanced queries support multiple comparison operators as seen here.

## Finding log entries, set the time range

Google Cloud

If you're looking for a specific set of log entries and have a rough idea when they would have been generated, start by narrowing to a specific time range. You can select one of the pre-created choices, set a custom range, or jump to a particular time +/- an amount.

## You can also manually restrict the time range

Google Cloud

You can also manually restrict the time range using the `timestamp` keyword, a comparator, and a time in RFC 3339 format.

## Finding entries quickly

### Search on an indexed field

- `httpRequest.status, logName, operation.id, resource.type, timestamp, severity, resource.labels`

### Be specific about the logs you are searching

- `logName="projects/benkelly-test/logs/apache-access"`

### Limit the time range you are searching

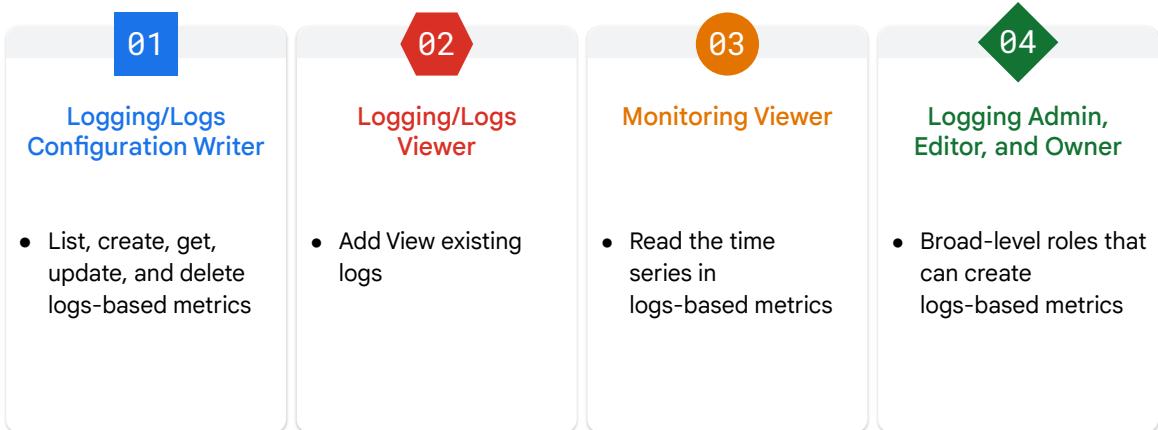

- `timestamp >= "2018-08-08T10:00:00Z" AND timestamp <= "2018-08-08T10:10:00Z"`

Google Cloud

Some tips on finding log entries quickly:

- Search for specific values of indexed fields, like the log entry name, resource type, and resource labels.
- As seen in the example, be specific on which logs you are searching by referring to it or them by name.
- Limit the time range you are searching to lessen the log data being queried.

## Key access control roles

Google Cloud

A refresher of the key IAM roles that relate to logging and monitoring.

First, on the logging side:

- **Logs Configuration Writers** can list, create, get, update, and delete logs-based metrics.
- **Logs Viewers** can view existing metrics.

On the monitoring side, **Monitoring Viewers** can read the time series in logs-based metrics.

And finally, **Logging Admins**, **Editors**, and **Owners** are all broad-level roles that can create logs-based metrics.

## Logs-based metrics

Google Cloud

**Logs-based metrics** are [Cloud Monitoring](#) metrics that are based on the content of log entries.

Resources generate logging events that are streamed into Google Cloud Logging.

## Logs-based metrics

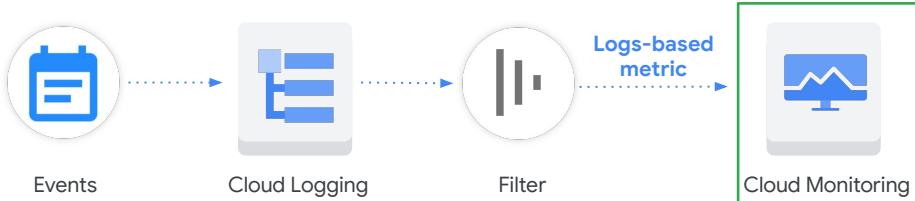

Google Cloud

Logs-based metrics apply a **filter** to locate particular entries.

For example, the metrics might record the number of log entries containing particular messages, or that were generated by a particular resource.

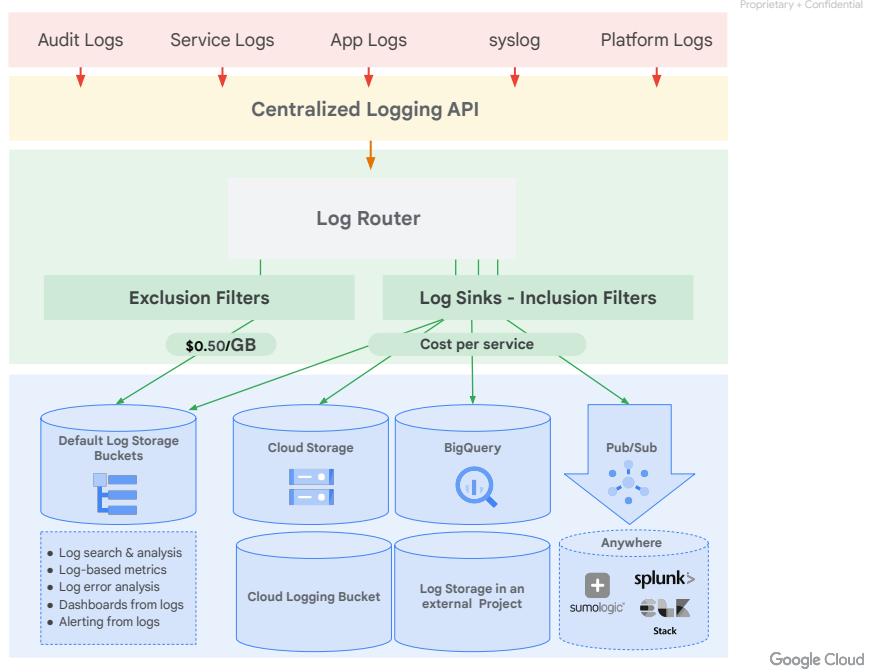

## Logs-based metrics

Google Cloud

Once created, you can use logs-based metrics in Cloud Monitoring charts and alerting policies.

# Logging architecture

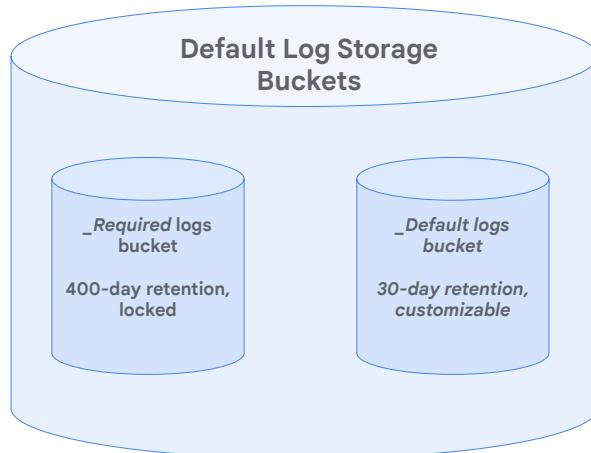

What we call Google Cloud Logging is actually a collection of components exposed through a centralized logging API. Entries are passed through the API and fed to the Log Router. Log Router is optimized for processing streaming data, reliably buffering it, and sending it to any combination of Log Storage and sink (export) locations.

By default, log entries are fed into one of the default log storage buckets. Exclusion filters may be created to partially or totally prevent this behavior.

Log Sinks run in parallel with the default log flow and may be used to direct entries to external locations, including additional Cloud Logging Buckets, Cloud Storage, BigQuery, Pub/Sub, or external projects.

Inclusion and exclusion filters can control exactly which logging entries end up at a particular destination, and which are ignored completely.

## Default logs buckets

Google Cloud

For each Google Cloud project, Logging automatically creates two logs buckets: *\_Required* and *\_Default*, and corresponding log sinks with the same names. All logs generated in the project are stored in one of these two locations:

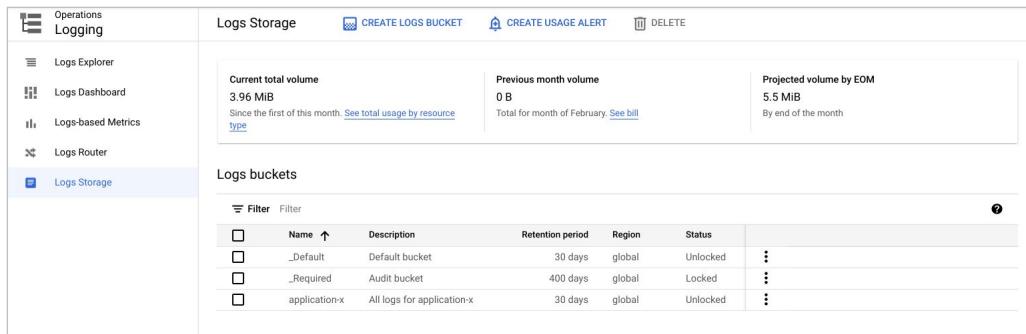

- *\_Required*: This bucket holds Admin Activity audit logs, System Event audit logs, and Access Transparency logs, and retains them for 400 days. You aren't charged for the logs stored in *\_Required*, and the retention period of the logs stored here cannot be modified. You cannot delete this bucket.
- *\_Default*: This bucket holds all other ingested logs in a Google Cloud project, except for the logs held in the *\_Required* bucket. Standard Cloud Logging [pricing](#) applies to these logs. Log entries held in the *\_Default* bucket are retained for 30 days, unless you apply [custom retention](#) rules. You can't delete this bucket, but you can [disable the \*\\_Default\* log sink that routes logs to this bucket](#).

Use gcloud to adjust the retention:

```
gcloud beta logging buckets update _Default
--location=global --retention-days=[RETENTION_DAYS]
```

**Note:** Effective March 31, 2021, storage costs will apply to all chargeable logs retained longer than the [default retention periods](#) at the rate of \$.01 per GiB per month (or fraction thereof). For details, see [Logs storage pricing](#).

# Create specialized buckets in current or remote projects

The screenshot shows the Google Cloud Logs Storage interface. On the left, there's a sidebar with icons for Logs Explorer, Logs Dashboard, Logs-based Metrics, Logs Router, and Logs Storage (which is selected). The main area has tabs for Logs Storage, Create Logs Bucket, Create Usage Alert, and Delete. Below these are sections for Current total volume (3.96 MiB), Previous month volume (0 B), and Projected volume by EOM (5.5 MiB). A table titled 'Logs buckets' lists four entries:

	Name	Description	Retention period	Region	Status	⋮
<input type="checkbox"/>	_Default	Default bucket	30 days	global	Unlocked	⋮
<input type="checkbox"/>	_Required	Audit bucket	400 days	global	Locked	⋮
<input type="checkbox"/>	application-x	All logs for application-x	30 days	global	Unlocked	⋮

Google Cloud

Logs buckets are containers in your Google Cloud projects that hold your logs data. You can create logs sinks to route all, or just a subset, of your logs to any logs bucket. This flexibility allows you to choose which Google Cloud project your logs are stored in and what other logs are stored with them. Log buckets may also be placed in specific regions for regulatory compliance. Using the gcloud command-line tool and the Google Cloud Console, you can create, update, and delete your custom logs buckets.

# Resource usage

The screenshot shows the Google Cloud Logs Storage interface. On the left, a sidebar menu includes Operations Logging, Logs Explorer, Logs Dashboard, Logs-based Metrics, Logs Router, and Logs Storage (which is selected). The main area has tabs for Logs Storage, Create Logs Bucket, Create Usage Alert, and Delete. A red box highlights the top section displaying resource usage statistics:

Current total volume 3.96 MiB Since the first of this month. See total usage by resource type	Previous month volume 0 B Total for month of February. See bill	Projected volume by EOM 5.5 MiB By end of the month
---	---	---

Below this, a table lists 'Logs buckets' with columns: Name (sorted), Description, Retention period, Region, Status, and three vertical ellipsis icons. The data is as follows:

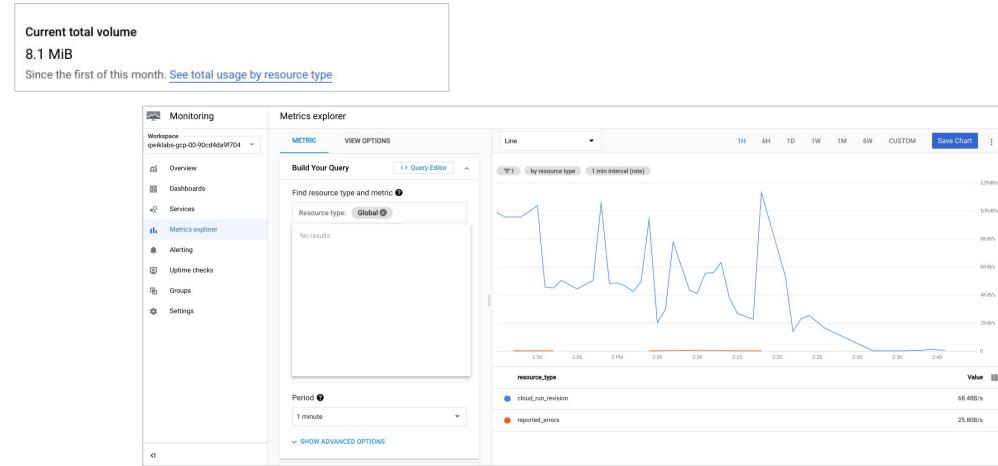

Name	Description	Retention period	Region	Status	⋮
_Default	Default bucket	30 days	global	Unlocked	⋮
_Required	Audit bucket	400 days	global	Locked	⋮
application-x	All logs for application-x	30 days	global	Unlocked	⋮

Google Cloud

The top of the Logs Storage page displays a summary of statistics for the logs that your project is receiving, including:

- **Current total volume:** The amount of logs your project has received since the first date of the current month.
- **Previous month volume:** The amount of logs your project received in the last calendar month.
- **Projected volume by EOM:** The estimated amount of logs your project will receive by the end of the current month, based on current usage.

# Resource usage

Google Cloud

You can view the total usage by resource type for the current total volume. The link opens Metrics Explorer, which allows you to build charts for any metric collected by your project.

For more information on using Metrics Explorer, see  
<https://cloud.google.com/monitoring/charts/metrics-explorer>.

# Exclusions: Identify log entries

The screenshot shows the Google Cloud Logs Explorer interface. At the top, there are navigation links: SHARE LINK, LAST 1 HOUR, PAGE LAYOUT, and LEARN. Below that is a 'Query preview' section with the query text `textPayload:"/score called"`. There are buttons for Save, Stream logs, and Run query. The main area is titled 'Query results' and shows a table of log entries. The columns are SEVERITY, TIMESTAMP (CST), and SUMMARY. The table contains 18 rows of log entries, all of which have a severity of INFO and a timestamp between 2021-02-01 14:23:22 and 2021-02-01 14:23:26. The 'SUMMARY' column shows repeated log entries with the pattern `/score called, score:<value>, containerID:<id>`, where <value> and <id> vary slightly across the rows.

SEVERITY	TIMESTAMP	CST	SUMMARY
INFO	2021-02-01	14:23:22.174 CST	/score called, score:70, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:22.174 CST	/score called, score:33, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:24.251 CST	/score called, score:32, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:24.439 CST	/score called, score:46, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.064 CST	/score called, score:58, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.261 CST	/score called, score:22, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.436 CST	/score called, score:6, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.589 CST	/score called, score:39, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.733 CST	/score called, score:71, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:25.878 CST	/score called, score:39, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:26.008 CST	/score called, score:55, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:26.141 CST	/score called, score:73, containerID:544f1660-64cb-11eb-b152-4f353cf2...
INFO	2021-02-01	14:23:26.282 CST	/score called, score:94, containerID:544f1660-64cb-11eb-b152-4f353cf2...

Google Cloud

Use **Logs Explorer** to build a query that selects the logs you want to exclude.

Save the query to use when building the exclusion.

## Exclusions: Edit the target log sink

The screenshot shows the Google Cloud Operations Logging interface. On the left, there's a sidebar with icons for Logs Explorer, Logs Dashboard, Logs-based Metrics, Logs Router (which is selected and highlighted in blue), and Logs Storage. The main area is titled "Logs Router" with "Logs Router Sinks" below it. It includes "CREATE SINK" and "DELETE" buttons and a "LEARN" link. A "Filter" section is present. The table lists two sinks:

Enabled	Type	Name	Description	Destination
<input type="checkbox"/>	Cloud Logging bucket	_Default		logging.googleapis.com/projects/qwiklabs-c013d04d7c857055/locat
<input checked="" type="checkbox"/>	Cloud Logging bucket	_Required		logging.googleapis.com/p/c013d04d7c857055/locat

A context menu is open on the right side of the second sink row, listing options: "View sink details", "Edit sink" (with a pencil icon), "Disable sink", and "Delete sink".

Google Cloud

Use the "hamburger menu" to the right of the target log sink to initiate editing of that entity

Take care here, because excluded log events will be lost forever.

## Exclusions: Build the exclusion

Choose logs to filter out of sink (optional)

Create exclusion filters to determine which logs are excluded from logs routing sink.

Exclusion filter name \*  
exclude-most-scores

19/100

Exclusion filter rate  
95

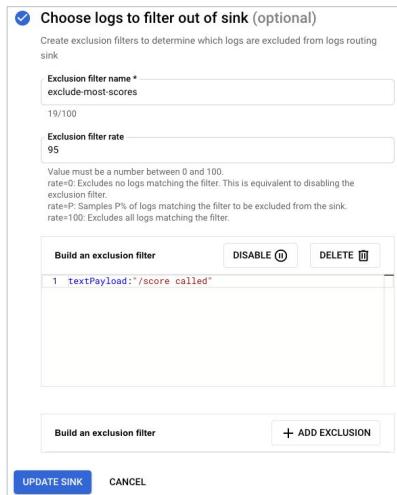

Value must be a number between 0 and 100.  
rate=0: Excludes no logs matching the filter. This is equivalent to disabling the exclusion filter.  
rate=P: Samples P% of logs matching the filter to be excluded from the sink.  
rate=100: Excludes all logs matching the filter.

Build an exclusion filter      DISABLE      DELETE

1 `textPayload:"/score called"`

Build an exclusion filter      + ADD EXCLUSION

UPDATE SINK      CANCEL

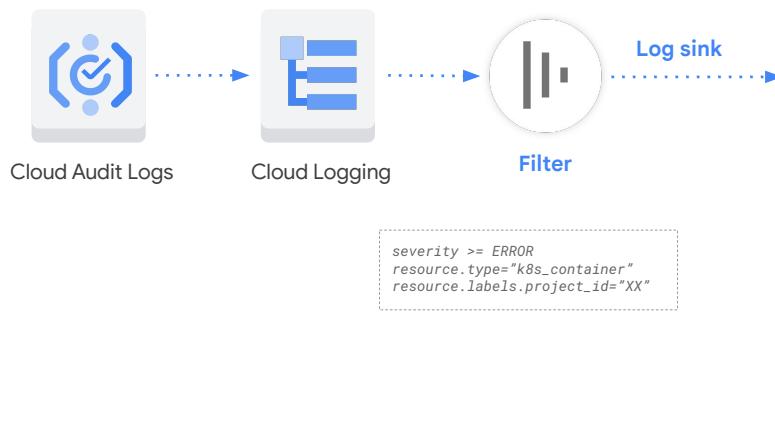

Google Cloud

Use the **Log Explorer** query to create an exclusion filter that filters the unwanted entries out of the sink. Give the exclusion a name and description and decide the percentage of log entries to exclude.

It might be helpful to leave some representative events, depending on the exclusion.

Create the exclusion and it will go into effect immediately.

## Log router sinks

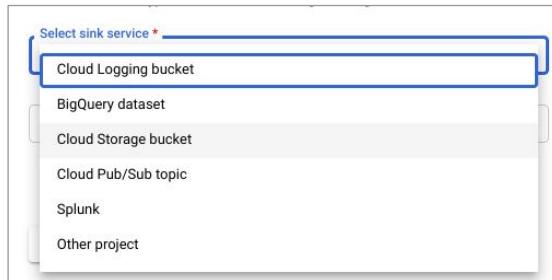

Google Cloud

Logs router sinks can be used to forward copies of some or all of your log entries to non-default locations. Use cases include storing logs for extended periods, querying logs with SQL, and access control.

Here, you see we've started creating a sink by creating a logs query for a particular subset of entries. We will pass that subset to one of the available sink locations.

## There are several sink locations, depending on need

Google Cloud

There are several sink locations, depending on need:

- **Cloud Logging bucket** works well to help pre-separate log entries into a distinct log storage bucket.
- **BigQuery dataset** allows the SQL query power of BigQuery to be brought to bear on large and complex log entries.
- **Cloud Storage bucket** is a simple external Cloud Storage location, perhaps for long-term storage or processing with other systems.
- **Cloud Pub/Sub topic** can export log entries to message handling third-party applications or systems created with code and running somewhere like Dataflow or Cloud Functions.
- **Splunk** for integration of logs into existing Splunk-based system.
- **Other project** is useful to help control access to a subset of log entries.

## Cloud Storage works well for general storage

Cloud storage works well for general log storage. It allows the control of bucket location, storage class, object lifecycle rules, and bucket locks. The files can also be easily processed with a number of tools and products.

## BigQuery for easy warehousing and analysis

BigQuery is a common log sink because it allows both long-term, cost-effective storage and the ability to implement powerful analytics with SQL queries. BigQuery also supports analysis with machine learning, and works well as a back end for visualization.

## Pub/Sub to connect with external systems and applications

Pub/Sub allows logging events to be streamed asynchronously to code, event processing pipelines created in Cloud Functions, Cloud Run, or Dataflow, or to third-party log analysis tools.

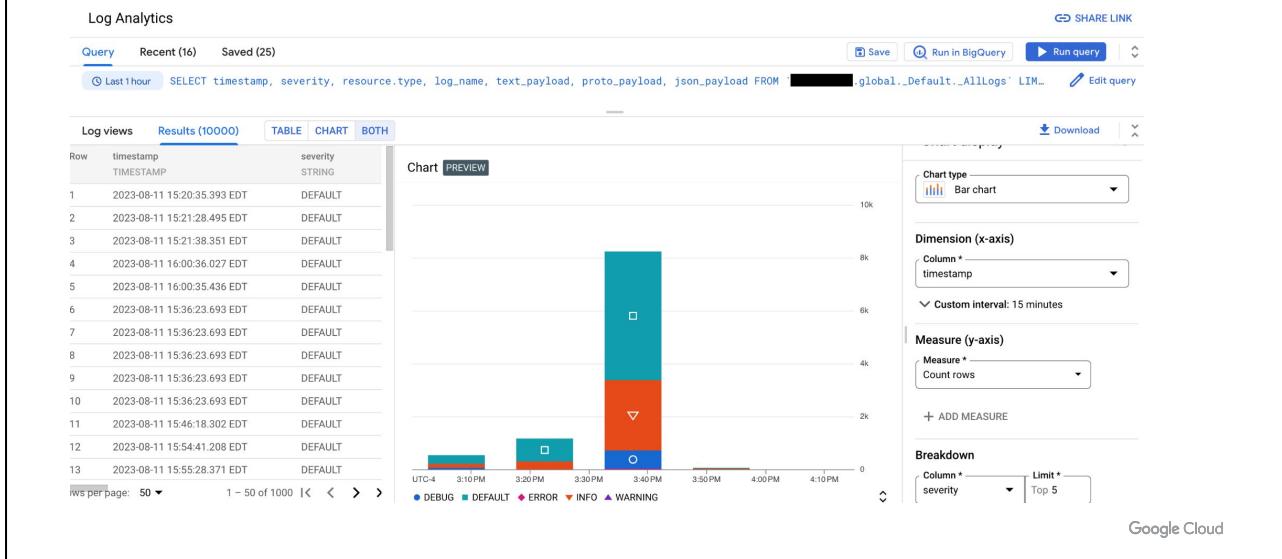

## Log exports

Google Cloud

Using a specialized bucket or external project is a great way to limit access and to control log entry location.

# Log Analytics: Use SQL to query your logs

Log Analytics is an alternative way of viewing and querying your logs. You query the logs using the SQL language, as shown above.

<https://cloud.google.com/logging/docs/log-analytics#analytics>

## Monitoring Network Security and Audit Logs

In this module, let's spend some time analyzing the Google Cloud Virtual Private Cloud.

# Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring
- 06 Network Intelligence Center

## VPC Flow Logs record a sample of network flows

Google Cloud

VPC Flow Logs record a sample of network flows sent from and received by VM instances, as you can see in this animation.

These logs can be used for network monitoring, forensics, real-time security analysis, and expense optimization.

Google Cloud is unique for its near real-time visibility, providing log updates every 5 seconds. Also, there is no extra delay and no performance penalty in routing the logged IP packets to their destination.

DNS provides a lookup for sites on the internet. You can think of it as a phone book, but instead of using the name of an organization to look up its phone number, you use the name of an organization to find an IP address. A DNS service is provided by your ISP (internet service provider).

For example, suppose a request comes from a client computer to access cymbal.com. To direct the client computer to the cymbal.com site, the internet service provider needs the IP address of cymbal.com. The ISP connects to get this information from its DNS service. The DNS service recursive resolver issues a request to look up the IP address of cymbal.com from one of its name servers. The name server responds with the ISP.

## Enable VPC Flow Logs per VPC subnet

Field	Type	Description
src_ip	string	Source IP address
src_port	int32	Source port
dest_ip	string	Destination IP address
dest_port	int32	Destination port
protocol	int32	IANA protocol number

Other fields:

- Start/end time
- bytes/packets sent
- Instance details
- VPC details
- Geographic details

Cloud Logging

Google Cloud

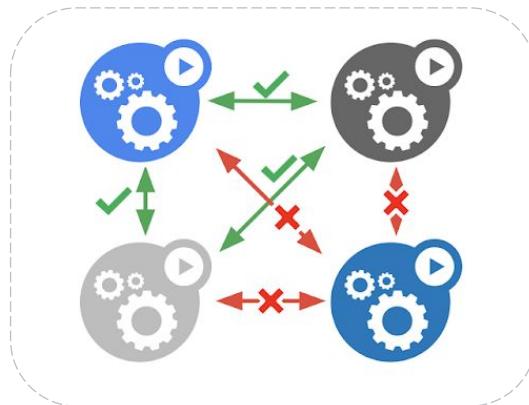

You can enable or disable VPC Flow Logs per VPC subnet. Once enabled for a subnet, VPC Flow Logs collect data from all VM instances in that subnet.

Each log entry contains a record of different fields. For example, this table illustrates the IP connection information that is recorded. This consists of the source IP address and port, the destination IP address and port, and the protocol number. This set is commonly referred to as 5-tuple.

Other fields include the start and end time of the first and last observed packet, the bytes and packets sent, instance details, VPC details, and geographic details.

For more information on all data recorded by VPC Flow Logs, please refer here:  
[https://cloud.google.com/vpc/docs/using-flow-logs#logs\\_collection](https://cloud.google.com/vpc/docs/using-flow-logs#logs_collection)

## VPC Firewalls

Google Cloud

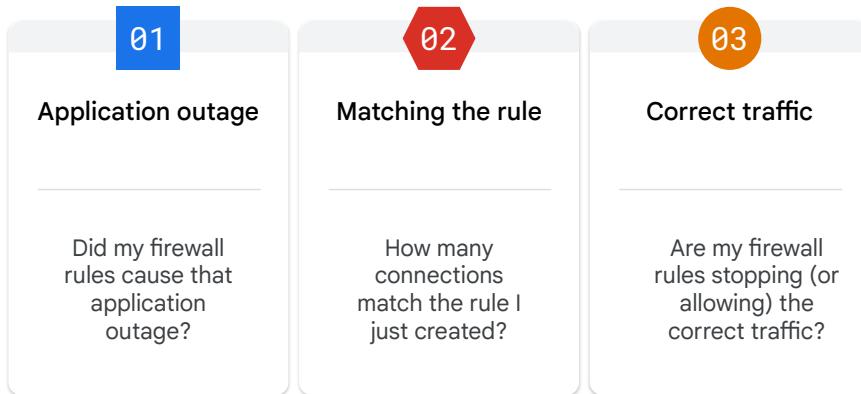

VPC firewall rules let you allow or deny connections to or from your virtual machine (VM) instances based on a configuration that you specify.

Enabled VPC firewall rules are always enforced, protecting your instances regardless of their configuration and operating system, even if they have not started up.

# Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring
- 06 Network Intelligence Center

# Firewall Rules Logging

Google Cloud

VPC firewall rules let you allow or deny connections to or from your virtual machine (VM) instances based on a configuration that you specify.

Enabled VPC firewall rules are always enforced, protecting your instances regardless of their configuration and operating system, even if they have not started up.

Firewall Rules Logging allows you to audit, verify, and analyze the effects of your firewall rules.

It can help answer questions like:

- Did my firewall rules cause that application outage?
- How many connections match the rule I just created?
- Are my firewall rules stopping (or allowing) the correct traffic?

See the Firewall Rule Logging [documentation](#) for details.

# Enabling Firewall Rules Logging in the console

- Firewall Rules Logging is **disabled** by default
- You enable it on a per-rule basis

The screenshot shows the 'Firewall rule details' page for a rule named 'enable-rdp'. The rule has the following configuration:

- Description:** An empty text input field.
- Logs:** A note stating that turning on firewall logs can generate a large number of logs which can increase costs in Stackdriver. It includes a 'Learn more' link and radio buttons for 'On' (unchecked) and 'Off' (checked).
- Network:** Set to 'default'.
- Priority:** Set to 1000.
- Direction:** Set to 'Ingress'.
- Action on match:** Set to 'Allow'.

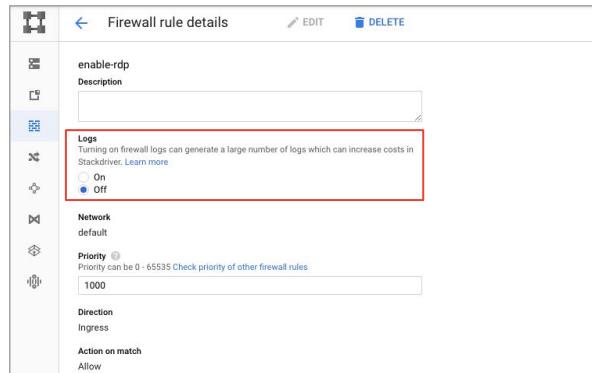

Google Cloud

By default, Firewall Rules Logging is disabled.

You can enable it on a per-rule basis.

# Enabling Firewall Rules Logging in the console

- Firewall Rules Logging is **disabled** by default
- You enable it on a per-rule basis

Google Cloud

In the slide screenshot, the user is editing the firewall rule named *enable-rdp*. Selecting the radio button will enable firewall rules.

**Caution:** Firewall Rules Logging can generate a lot of data which may have a cost impact.

## Enabling Firewall Rules Logging in the CLI

- Firewall Rules Logging can also be enabled or disabled using the following **gcloud** commands:
- Substitute [NAME] for the name of your firewall rule

### Enable:

```
gcloud compute firewall-rules update [NAME] --enable-logging
```

### Disable:

```
gcloud compute firewall-rules update [NAME] --no-enable-logging
```

Google Cloud

Firewall Rules Logging can also be enabled on existing firewall rules using the CLI.

See these two examples on this slide. In both, [NAME] would be the name of your firewall rule.

# Viewing the Firewall Rules logs

- In Logging, you can view the logs in real time
- Or, export the firewall logs to a BigQuery sink

Cloud Logging

BigQuery

The screenshot shows the Google Cloud Logs Explorer interface. At the top, there's a search bar and various filter options like 'OPTIONS', 'REFINE SCOPE', and 'Project'. Below that is a 'Logs Explorer' section with tabs for 'Recent (8)', 'Saved (0)', and 'Suggested (1)'. A query builder is active, showing a search term 'logName="prj..."' and a dropdown menu for 'Select log names' containing several log types: CLOUD AUDIT, activity, data\_access, compute ENGINE, activity\_log, firewall, shielded\_vm\_integrity, and vpc\_flows. On the right side, a log entry is displayed in a card format with timestamp 'Feb 1, 3:44 PM', source 'compute.googleapis.com[2FFfirewall]', and details: '2021-02-01 15:43:12.196 CST' and 'IAM k8s.io.io.k8s.core.v1.secrets.create -'. The bottom of the interface shows a summary of log entries.

Google Cloud

Like all Google Cloud Logs, use Logs Explorer to view logs in real time, or to configure exports.

BigQuery is frequently used to simplify firewall rules log analysis.

# Viewing the Firewall Rules logs

- In Logging, you can view the logs in real time
- Or, export the firewall logs to a BigQuery sink

Cloud Logging

BigQuery

The screenshot shows the Google Cloud Logs Explorer interface. The search bar at the top contains the query `logName="firewall"`. The results pane displays a list of log entries. One entry is highlighted, showing a timestamp of `2021-02-01 15:43:12.196 CST`, an IAM role of `k8s.io`, and a method of `io.k8s.core.v1.secrets.create`.

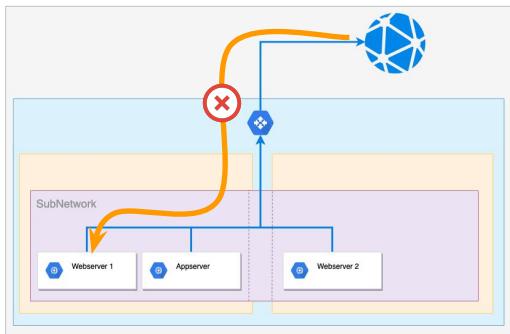

Google Cloud

Like all Google Cloud Logs, use Logs Explorer to view logs in real time, or to configure exports.

BigQuery is frequently used to simplify firewall rules log analysis.

# Firewall Rules provide microsegmentation

Segmentation/Gateway-centric

Google Cloud

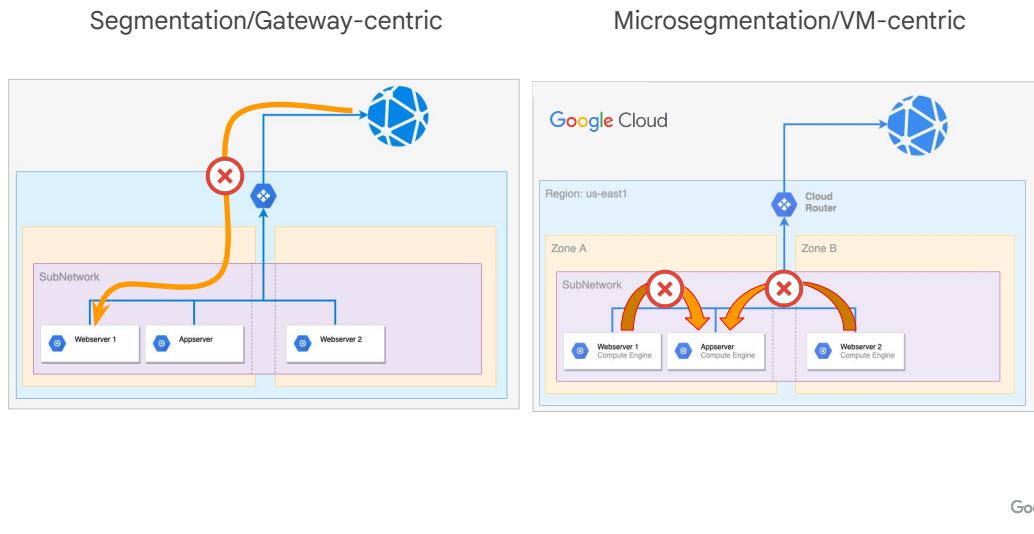

A lot of users are familiar with classic segmentation or gateway-centric firewalls.

In this example, you can see a private network, possibly at your office or home.

At the network boundary, where the private network meets the outside internet, sits a firewall.

A segmentation firewall is designed to segment and secure a protected network from an outside insecure network.

# Firewall Rules provide microsegmentation

Google Cloud VPC Firewalls are micro-segmentation firewalls.

These function more like a bunch of micro-firewalls, each sitting on the NIC of every VM connected to the VPC.

The micro-firewalls can then grant or deny any configured incoming or outgoing traffic.

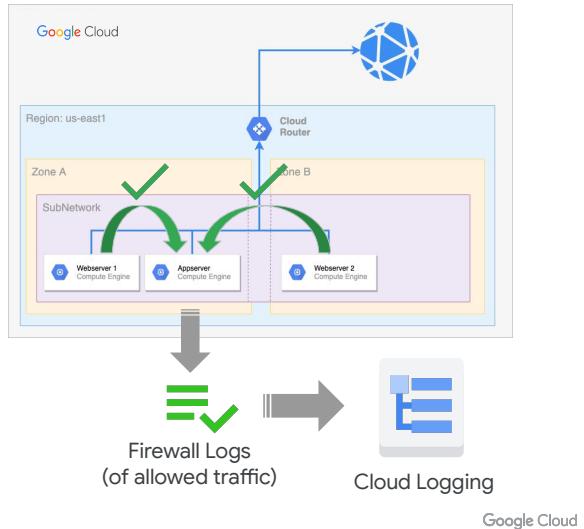

Now, imagine we have an issue.

We have two different web servers, and after some configuration changes by a particular DevOps team, the web servers can no longer access the application server they both share.

How can we tell if this is a firewall-related issue? Let's see.

## Troubleshooting: using rules to catch incorrect traffic

- Logging all denied connections will create too many log entries
- Temporarily create a low-priority rule to allow traffic to the server
  - Enable logging
- If traffic now gets through, examine the logs as to why

If the connectivity issue is related to a firewall, then there are two major possibilities.

1) There's a firewall rule that's actively blocking the incoming connections from the web servers.

Or

2) Since network traffic is blocked by default in most networks, there could be a firewall rule that isn't allowing the traffic from the web servers as it should.

Two sides of the same coin.

Logging all denied connections could generate a lot of data that would take time and effort to go through. So, instead of starting with option one, let's start with option two.

Create a temporary low-priority rule specifically designed to allow the web server traffic through to the app server. Enable logging on it so you can examine the entries.

Suddenly the traffic is getting through, so you know it's firewall related. Now examine the log entries. Also, find the existing rule that's supposed to be allowing the traffic and see what you can find out.

Hey, look at that! The rule that's supposed to be allowing the traffic is based on a network tag named `webserver`, and the web server machines are actually using the

network tag *web-server*. There it is, that's your problem.

## Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring
- 06 Network Intelligence Center

# The internal and external HTTP(s) load balancers support logging

- Enabled on a per backend service basis
  - URL map may reference more than one
  - Will have to enable for each
- Enabled by default

**Edit backend service**

Name: k8s-be-31624-a20d93e6082ea0c3

Description:

Backend type: Instance group

Protocol, named port & timeout

Protocol	Named port	Timeout
HTTP	port31624	30 seconds

Backends

Regions: us-central1

k8s-ig-a20d93e6082ea0c3 (Zone: us-central1-c, Port: 3... Not saved)

+ Add backend

Cloud CDN

Enable Cloud CDN

Health check

k8s-be-31624-a20d93e6082ea0c3 (HTTP)  
port: 31624, timeout: 60s, check interval: 60s, unhealthy threshold: 10 attempts

Logging

Enable logging

Google Cloud

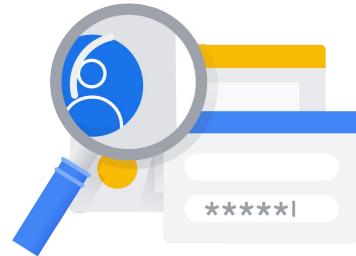

You can enable logging on a per backend service basis. A single internal HTTP(S) load balancer URL map can reference more than one backend service, so you might need to enable logging for more than one backend service, depending on your configuration. It will be enabled by default for all new load balancers backends, but backends created before the GA release of load balancer logging may require manual configuration.

# Log entries

Types of information

Log entries contain the following types of information:

- General information including:
  - Severity, project ID, project number, and timestamp.
- `HttpRequest` log fields, including:
  - Method, URL, status, remote IP, and user agent.
- A `statusDetails` containing a string explaining why the load balancer returned the HTTP status that it did, cache and failure information.
- Redirects (HTTP response status code 302 found) issued from the load balancer are not logged. Redirects issued from the backend instances are logged.

Google Cloud

HTTP(S) load balancing log entries contain information useful for monitoring and debugging your HTTP(S) traffic. Make sure to [check the documentation for details](#).

Log entries contain the following types of information:

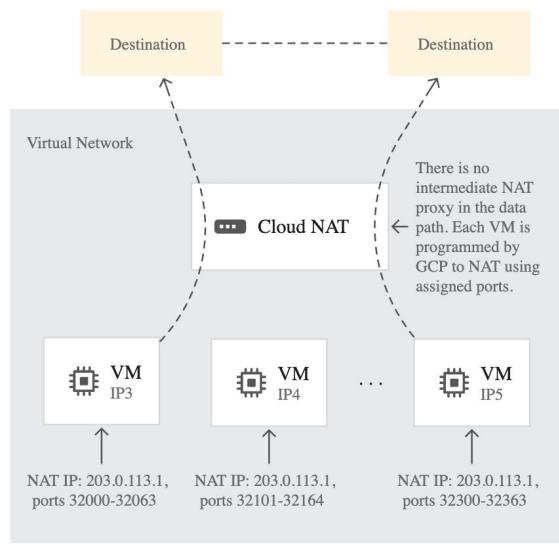

- General information shown in most logs, such as severity, project ID, project number, timestamp, and so on.
- `HttpRequest` log fields. However, `HttpRequest.protocol` is not populated for HTTP(S) load balancing Cloud Logging logs.
- A `statusDetails` field inside the `structPayload`. This field holds a string that explains why the load balancer returned the HTTP status that it did.
- Redirects (HTTP response status code 302 Found) issued from the load balancer are *not* logged. Redirects issued from the backend instances *are* logged.

## Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring
- 06 Network Intelligence Center

## Cloud NAT overview

- Allows GCE VMs with no external IP to send packets to the internet
- Fully managed, software defined, grounded in Andromeda
- Benefits include:
  - Security
  - Availability
  - Scalability
  - Performance

Google Cloud

Cloud NAT ([network address translation](#)) allows Google Cloud virtual machine (VM) instances without external IP addresses and private Google Kubernetes Engine (GKE) clusters to send outbound packets to the internet and receive any corresponding established inbound response packets.

Cloud NAT is a distributed, software-defined, fully managed service, grounded in the [Andromeda software](#) that powers your VPC network. It provides source network address translation (SNAT) for VMs without external IP addresses, as well as destination network address translation (DNAT) for established inbound response packets.

Cloud NAT benefits include:

- **Security:** You can reduce the need for individual VMs to have external IP addresses, lessening the surface area for attack. You can also confidently share a set of common external source IP addresses with a destination party.
- **Availability:** Cloud NAT is a distributed, software-defined, managed Google Cloud service. It doesn't depend on any VMs in your project or a single physical gateway device.
- **Scalability:** Cloud NAT can be configured to automatically scale the number of NAT IP addresses it uses, and it supports VMs that belong to managed instance groups, including those with [autoscaling](#) enabled.
- **Performance:** Cloud NAT does not reduce the network bandwidth per VM. Cloud NAT works directly with Google's Andromeda software-defined

- networking.

🔒 <https://cloud.google.com/>

Google Cloud

## Autoscaling groups of instances

For more information about autoscaling, visit the guide titled 'Autoscaling groups of instance' in the official Google Cloud documentation.

# Cloud NAT logging

- Allows you to log NAT **connections** and/or **errors**
  - TCP and UDP traffic only
  - 50-100 entries per second, per vCPU
- Enable logging by editing the Cloud NAT settings
- View by filtering Logs Explorer:
  - Resource: Cloud NAT Gateway
  - (optional) Restrict to region or NAT Gateway

## Advanced configurations

### Stackdriver logging

Export Cloud NAT logs to Stackdriver

- No logging
- Translation and errors
- Translation only
- Errors only

Google Cloud

Cloud NAT logging allows you to log NAT TCP and UDP connections and errors. When Cloud NAT logging is enabled, a log entry can be generated when a network connection using NAT is created, and/or when an egress packet is dropped because no port was available for NAT.

You can opt to log both kinds of events, or just one or the other. Logs contain TCP and UDP traffic only, and the log rate threshold will max out at 50-100 log events per vCPU before log filtering.

Cloud NAT logging may be enabled when a new Cloud NAT gateway is first created, or by editing an existing gateway's settings.

To view the collected logs in Logs Explorer, filter to the Cloud NAT Gateway resource and optionally, restrict to a particular region or Gateway.

The full query will look something like:

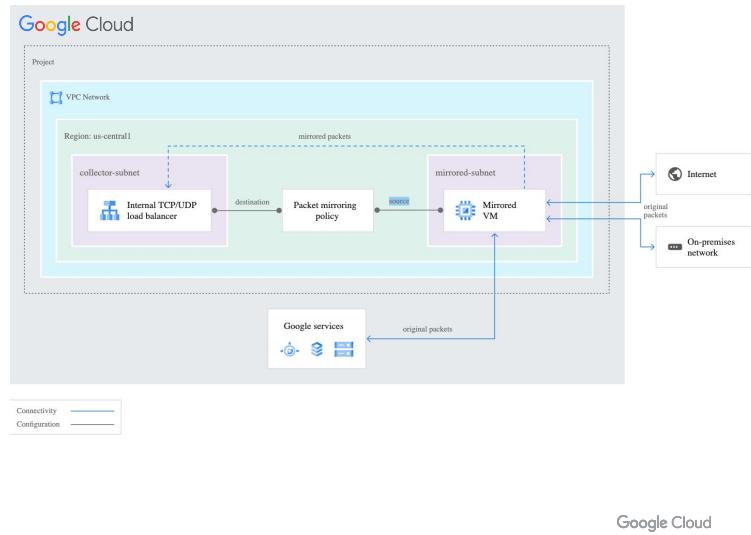

```
resource.type="nat_gateway"
logName="projects/{#project_id}/logs/compute.googleapis.com%2Fnat_flows"
```

## Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring
- 06 Network Intelligence Center

# Packet Mirroring: visualize and protect your network

- Clones VPC instance traffic and forwards for examination
- Happens at NIC not as part of VPC
- Can monitor and analyze security status
- Provides access to full traffic flow for regulatory or performance analysis

Packet Mirroring clones the traffic of specified instances in your Virtual Private Cloud (VPC) network and forwards it for examination. Packet Mirroring captures all ingress and egress traffic and packet data, such as payloads and headers.

The mirroring happens on the virtual machine (VM) instances, not on the network. Consequently, Packet Mirroring consumes additional bandwidth on the hosts.

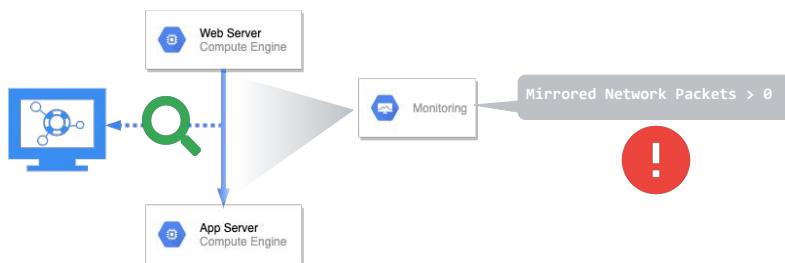

Packet Mirroring is useful when you need to monitor and analyze your security status. It exports all traffic, not only the traffic between sampling periods. For example, you can use security software that analyzes mirrored traffic to detect all threats or anomalies.

Additionally, you can inspect the full traffic flow to detect application performance issues and to provide network forensics for PCI compliance and other regulatory use cases.

Obviously, this can generate a lot of data, so the recommended target is a load-balanced Compute Engine Managed Instance Group or equivalent technology.

# Monitoring Packet Mirroring

- Metrics can verify that instances are being monitored as intended

Google Cloud

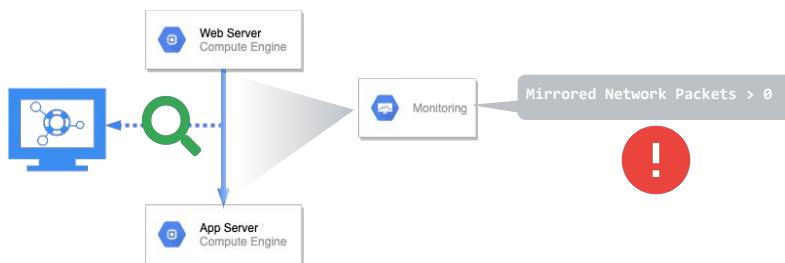

Packet Mirroring exports monitoring data about mirrored traffic to Cloud Monitoring.

You can use monitoring metrics to check whether traffic from a VM instance is being mirrored as intended.

For example, you can view the mirrored packet or byte count for a particular instance.

# Monitoring Packet Mirroring

- Metrics can verify that instances are being monitored as intended
  - Mirrored Packets count
  - Mirrored Bytes Count
  - Dropped Packets Count

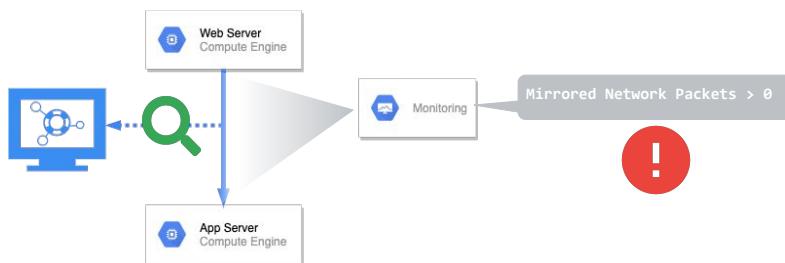

Google Cloud

You can view the monitoring metrics of mirrored VM instances or instances that are part of the collector destination (internal load balancer).

For mirrored VM instances, Packet Mirroring provides metrics specific to mirrored packets, such as `/mirroring/mirrored_packets_count`, `/mirroring/mirrored_bytes_count`, and `/mirroring/dropped_packets_count`.

# Monitoring Packet Mirroring

- Metrics can verify that instances are being monitored as intended
  - Mirrored Packets count
  - Mirrored Bytes Count
  - Dropped Packets Count
- Can also spot where packet mirroring shouldn't be happening

Google Cloud

Monitoring can also spot where packet mirroring is being used unnecessarily or unexpectedly.

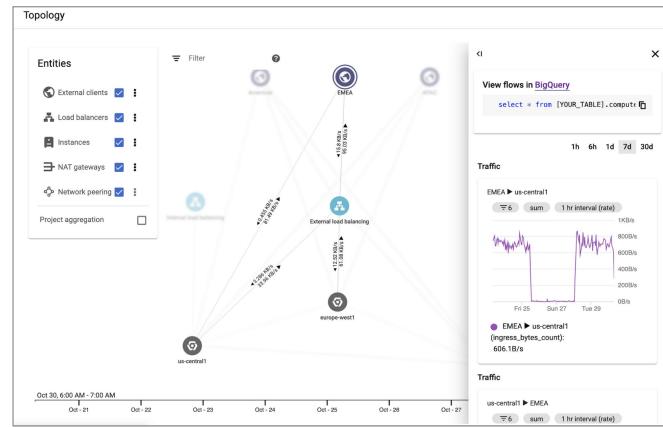

Keep in mind that, as noted, mirroring generates a lot of data that requires storage and processing, but also note that it slows the network throughput of the virtual machines being monitored and may accidentally expose sensitive data.

## Firewall Rules

- 01 VPC Flow Logs
- 02 Firewall Rules Logging
- 03 Load Balancer Logs
- 04 Cloud NAT Logs
- 05 Packet Mirroring

# Network Intelligence Center

Centralized Network monitoring and visibility

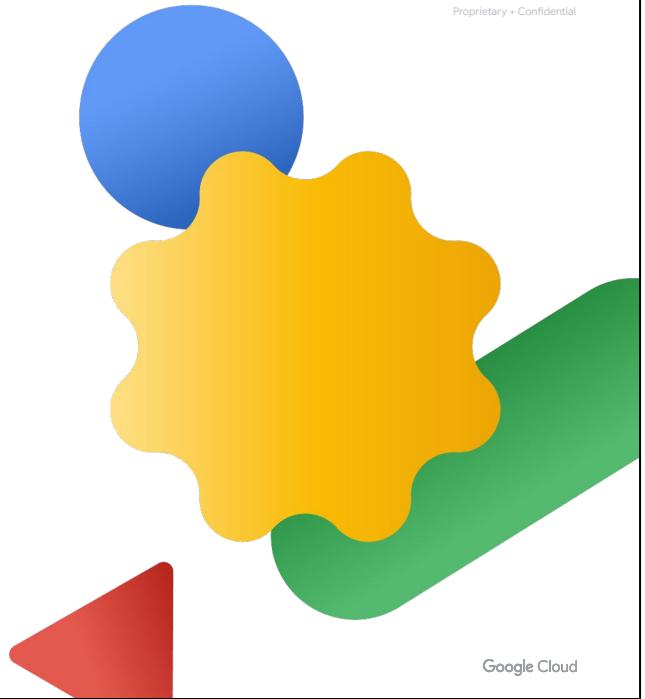

Google Cloud

Google's Network Intelligence Center is all about giving you centralized monitoring and visibility into your network, reducing troubleshooting time and effort, increasing network security, all while improving the overall user experience.

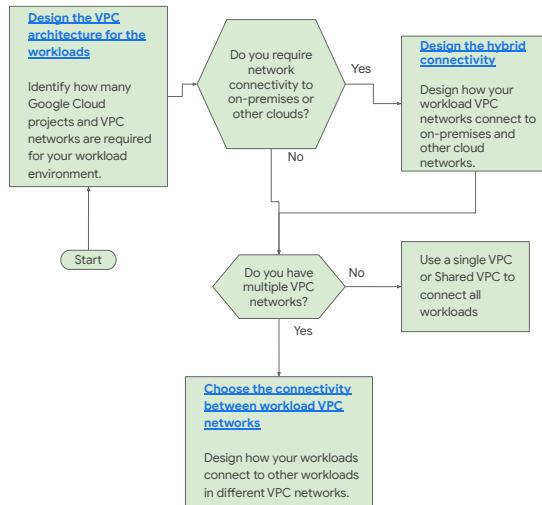

Currently, it offers four modules: network topology, connectivity testing, a performance dashboard, and firewall insights.

# Network Architecture Design Approach

BREAK SLIDE

# Network architecture design approach

Google Cloud

This slide deck introduces a design approach for cloud network architecture in Google Cloud. The goal is to design a foundational network topology that supports the deployment of future workloads. The network design can be approached in three distinct phases.

## 1) Designing the workload VPC architecture

It is important to identify at an early stage, how many projects and Virtual Private Cloud (VPC) networks are required to host your workloads.

Projects are fundamental grouping mechanisms in Google Cloud. A [project](#) contains related services and workloads that have a single administrative domain. A project is required to use Google Cloud, and forms the basis for creating, enabling, and using all Google Cloud services, managing APIs, enabling billing, adding and removing collaborators, and managing permissions.

Enterprises may have different administrative domains for their workload environments. For example, the Development team may manage all workloads in one project, and the Production team may manage their workloads in a separate project.

A project contains one or more VPC networks. A [VPC network](#) provides connectivity between Google Cloud workloads, and to external networks.

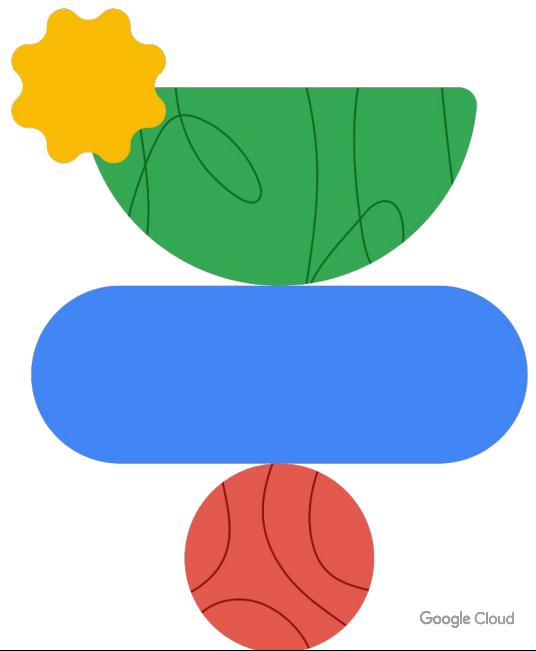

## 2) Designing the hybrid network connectivity

It is important to design a robust hybrid network topology that allows workload VPC networks to connect to on-premises networks, and other cloud networks. Many enterprises require hybrid connectivity to their on-premises datacenter workloads via an [Cloud Interconnect](#) or [VPN](#). Many enterprises also require multi-cloud connectivity to workloads running on other clouds.

## 3) Designing the connectivity between workload VPC networks

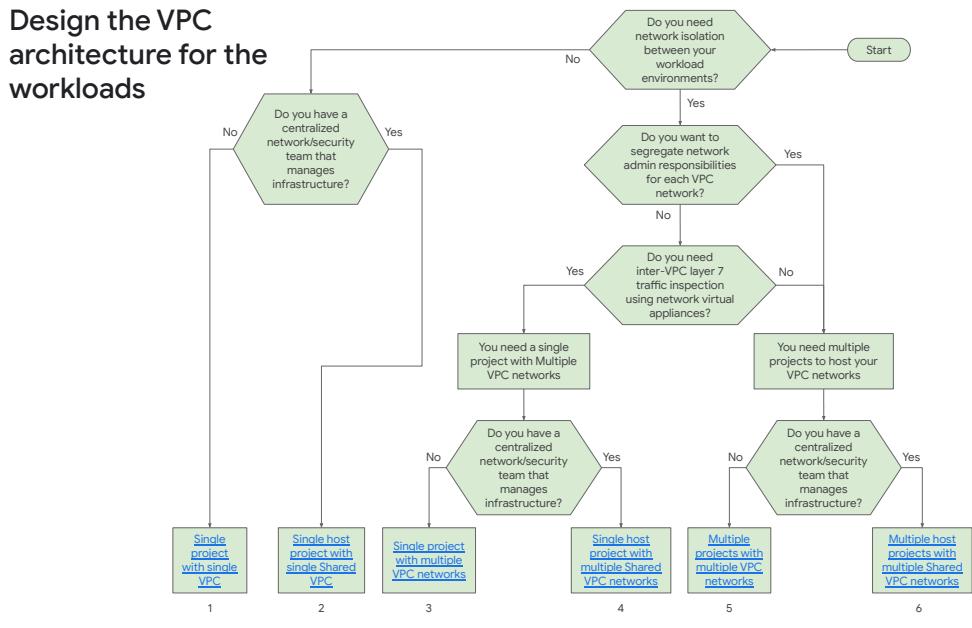

Multiple workload VPC networks in Google Cloud may require connectivity between each other. There are different ways to connect workloads depending on the workload type (i.e., IaaS, serverless or managed services). Learn more about [connecting multiple VPC networks](#).

# Designing the VPC Architecture for the Workloads

~~Note: These slides are sourced from the Partner Advantage document [Google Cloud Networking Design Patterns | Technical | Y22](#)~~

Welcome to this section: Design the VPC Architecture for the Workloads.

Google Cloud

## Identify how many Google Cloud projects and VPC networks are required for your workloads.

The number of projects and VPC networks depends on factors such as:

- ✓ The need for layer 7 traffic inspection of network traffic using third-party VM appliances
- ✓ The need for mitigation of data exfiltration (using VPC Service Control perimeters)
- ✓ The need for central network resource configuration and management

Use the decision tree to select the appropriate workload VPC architecture from the following options:

1. Single project with single VPC

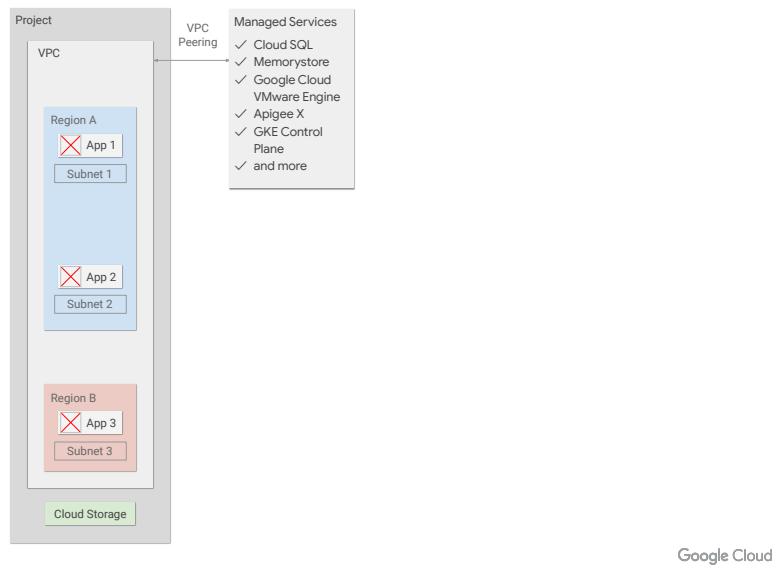

2. Single host project with single Shared VPC

- 3. Single project with multiple VPC networks
- 4. Single host project with multiple Shared VPC networks
- 5. Multiple projects with multiple VPC networks
- 6. Multiple host projects with multiple Shared VPC networks

# Designing the VPC Architecture for the Workloads

- 01 Single project with single VPC
- 02 Single host project with single Shared VPC
- 03 Single project with multiple VPC networks
- 04 Single host project with multiple Shared VPC networks
- 05 Multiple projects with multiple VPC networks
- 06 Multiple host projects with multiple Shared VPC networks

## 1. Single project with single VPC

Recommended to use when

### Network Security

1. You **do not need network isolation between applications**. All applications can reside in a single network.
2. Firewall rules inside a VPC network are sufficient to control network access between applications.
3. Identity and Access Management (IAM) permissions are sufficient to control access to cloud services.

### Network Operations

4. In a multi-team environment, application teams want **autonomy over the configuration of network resources** for their applications. A standalone VPC (rather than Shared VPC) can be used.

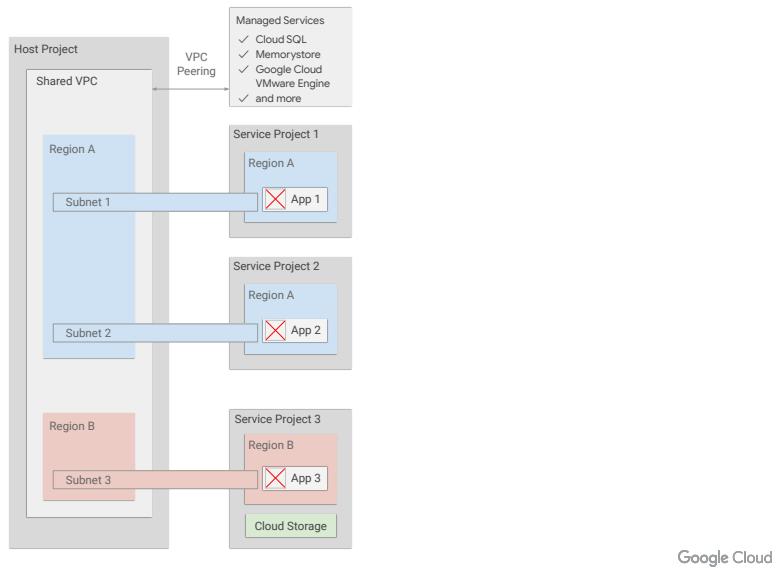

Recommended hybrid connectivity

Use the following hybrid connectivity for connecting to on-premises or other clouds:

# Designing the VPC Architecture for the Workloads

- 01 Single project with single VPC
- 02 Single host project with single Shared VPC
- 03 Single project with multiple VPC networks
- 04 Single host project with multiple Shared VPC networks
- 05 Multiple projects with multiple VPC networks
- 06 Multiple host projects with multiple Shared VPC networks

## 2. Single host project with single Shared VPC

Recommended to use when

### Network Security

1. You **do not need network isolation between applications**. All applications can reside in a single network.
2. Firewall rules inside a VPC network are sufficient to control network access between applications.
3. IAM permissions are sufficient to control access to cloud services

### Network Operations

4. In a multi-team environment, you want a network team to **centrally manage network resources in a common network**. Shared VPC allows application teams to deploy their applications in projects (Service Projects) that use network resources in a centrally managed network (Shared VPC).

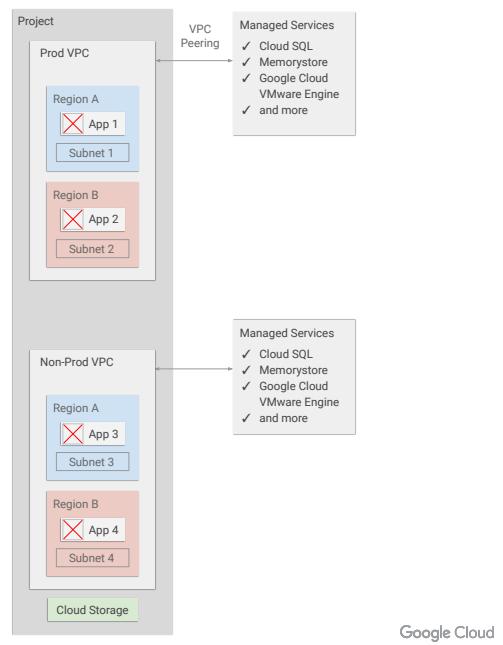

Recommended hybrid connectivity

Use the following hybrid connectivity for connecting to on-premises or to other clouds:

# Designing the VPC Architecture for the Workloads

- 01 Single project with single VPC
- 02 Single host project with single Shared VPC
- 03 Single project with multiple VPC networks
- 04 Single host project with multiple Shared VPC networks
- 05 Multiple projects with multiple VPC networks
- 06 Multiple host projects with multiple Shared VPC networks

### 3. Single project with multiple VPC networks

Recommended to use when

#### Network Security

1. You need **network isolation between workload environments** (typically required as part of network security compliance). For example, network isolation between Prod and Non-Prod workloads requires the workload applications to be deployed in separate VPC networks.
2. You may need a network virtual appliance (NVA) for **layer 7 traffic inspection between workload environments**. For example, layer 7 traffic inspection between Prod and Non-prod applications requires that the applications are in separate VPC networks.

#### Network Operations

3. Application teams want **autonomy over network resource configuration** for their applications. For example, if the Prod application team requires autonomy over network resource configuration, they can deploy their application and all associated networking configuration directly in the Prod VPC and not a Shared VPC.

Recommended hybrid connectivity

- [B. Hybrid connectivity to multiple VPC \(or Shared VPC\) networks](#)

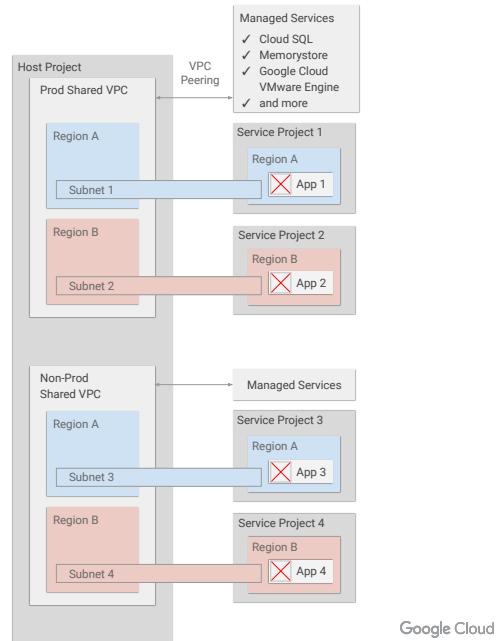

If you require layer 7 traffic inspection between the VPC networks, use the following:

- [C. Hybrid connectivity using appliances](#)

# Designing the VPC Architecture for the Workloads

- 01 Single project with single VPC
- 02 Single host project with single Shared VPC
- 03 Single project with multiple VPC networks
- 04 Single host project with multiple Shared VPC networks**
- 05 Multiple projects with multiple VPC networks
- 06 Multiple host projects with multiple Shared VPC networks

## 4. Single host project with multiple Shared VPC networks

Recommended to use when

### Network Security

1. You need **network isolation between workload environments** (typically required as part of network security compliance). For example, network isolation between Prod and Non-Prod workloads requires the workload applications to be deployed in separate VPC networks.
2. You may need a network virtual appliance (NVA) for **layer 7 traffic inspection between workload environments**. For example, layer 7 traffic inspection between Prod and Non-prod applications requires that the applications are in separate VPC networks.

### Network Operations

3. You require a network team to **centrally manage network resources in a common network**. Shared VPC allows application teams to deploy their applications in projects (Service Projects) that use network resources in a centrally managed network (Shared VPC).

Recommended hybrid connectivity

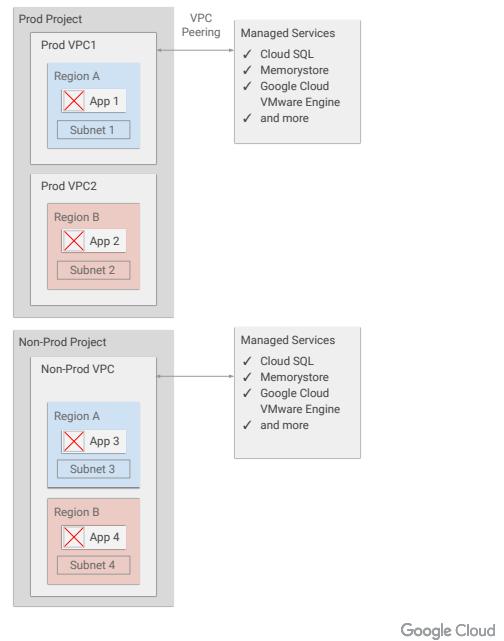

If you require layer 7 traffic inspection between the VPC networks, use the following:

- [C. Hybrid connectivity using appliances](#)

# Designing the VPC Architecture for the Workloads

- 01 Single project with single VPC
- 02 Single host project with single Shared VPC
- 03 Single project with multiple VPC networks
- 04 Single host project with multiple Shared VPC networks
- 05 Multiple projects with multiple VPC networks
- 06 Multiple host projects with multiple Shared VPC networks

## 5. Multiple projects with multiple VPC networks

Google Cloud

Recommended to use when

### Network Security

## Recommended hybrid connectivity

Use the following recommended hybrid connectivity for connecting your VPC networks to on-premises or other clouds:

- [B. Hybrid connectivity to multiple VPC \(or Shared VPC\) networks](#)

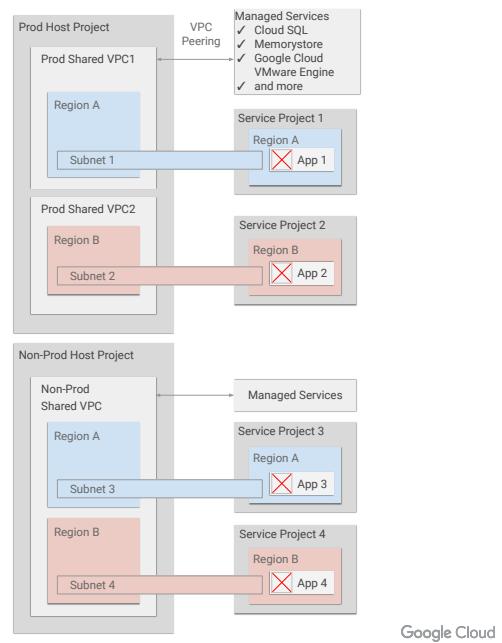

If you require layer 7 traffic inspection between the VPC networks, use the following:

- [C. Hybrid connectivity using appliances](#)

# Designing the Hybrid Connectivity

Google Cloud

# Design the hybrid connectivity

## Design the hybrid network topology for connecting workloads in your VPC network(s) to on-premises and other clouds.

The hybrid connectivity design depends on factors such as:

- ✓ The number of VPC networks used for the workloads
- ✓ The need for layer 7 traffic inspection of network traffic using network virtual appliances (NVA) appliances
- ✓ Access to Google-managed services that use [Private Services Access](#)

Use the decision tree as a quick guide in selecting the appropriate network topology.

The following network topology patterns are recommended:

A. [Hybrid connectivity to single VPC \(or Shared VPC\)](#)

B. [Hybrid connectivity to multiple VPC \(or Shared VPC\) networks](#)

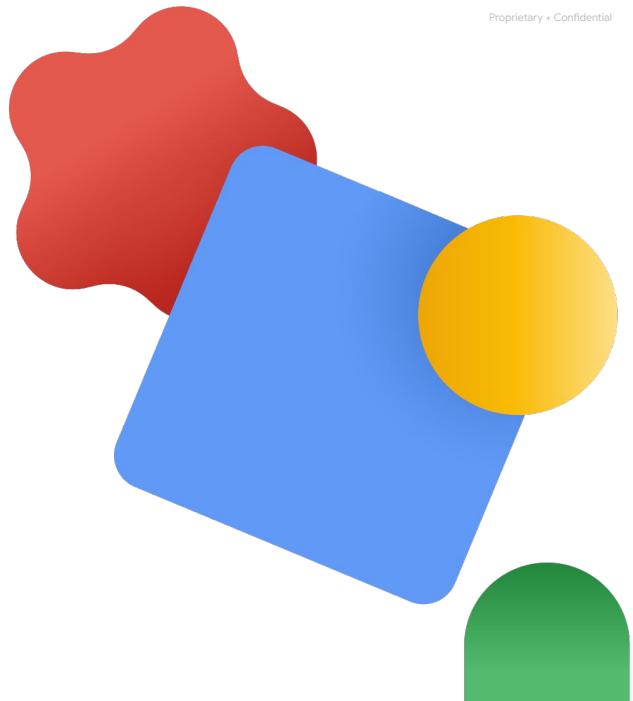

C. [Hybrid connectivity using appliances](#)

When you have a large number of workload VPC networks, you might need a hub and spoke architecture that supports a large number of VPC networks. This involves connecting multiple workload VPC networks to a transit Hub VPC that has connectivity to on-premises and other clouds. Consider the following network topology patterns and their associated pros and cons:

[D. Hub and Spoke with VPC Peering to Spokes](#)

[E. Hub and Spoke with HA-VPN to Spokes](#)

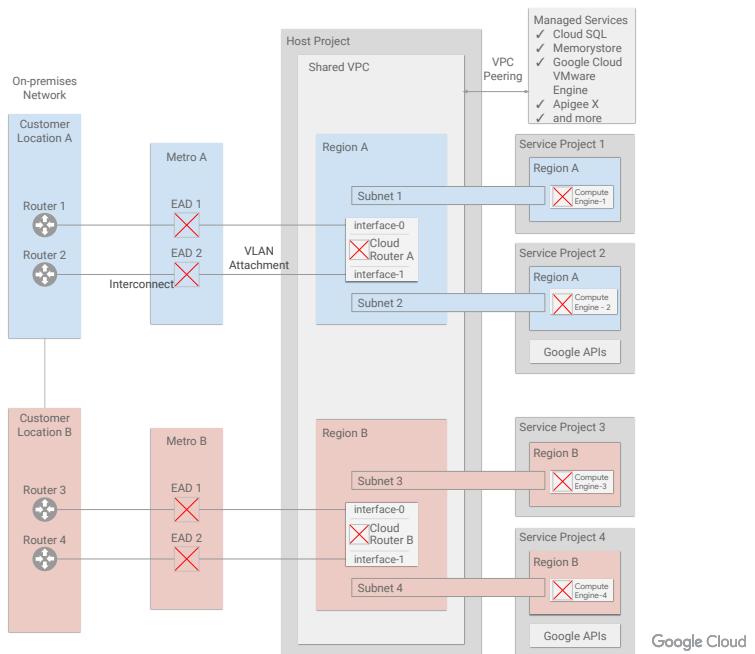

## Hybrid Connectivity to a Single VPC (for Shared VPC)

BREAK SLIDE

# A. Hybrid connectivity to single VPC (or Shared VPC)

## A1: Summary

## Abbreviation

EAD = [Edge Availability Domain](#)

Metro = [Metropolitan Area](#)

## Overview

The network design patterns in **Section A** apply to the following workload environments:

- ✓ [Single project with single VPC](#)
- ✓ [Single host project with single Shared VPC \(shown here\)](#)

In this network topology, Interconnect (or HA-VPN) from on-premises (or other clouds) terminates directly into a single Shared VPC.

This pattern provides hybrid connectivity to

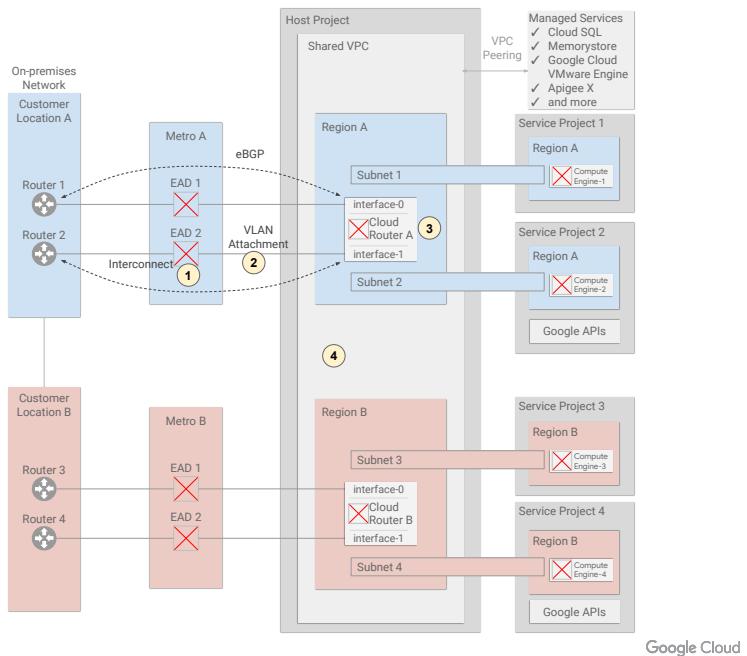

- ✓ IaaS resources in the workload Shared VPC
- ✓ Google APIs and services (for example, storage.googleapis.com , \*.run.app) in the service projects
- ✓ Google Cloud managed services that use [Private Services Access](#)

## Scaling Out

If your workload environment grows and you require more Host Projects and Shared VPC networks, you can expand this architecture as illustrated in **Section B** - [Hybrid connectivity to multiple VPC \(or Shared VPC\) networks.](#)

# A. Hybrid connectivity to single VPC (or Shared VPC)

A2: Interconnect to on-premises

## 1) Cloud Interconnect

Set up [Dedicated Interconnect](#) or [Partner Interconnect](#) to Google Cloud. Connect to two [Edge Availability Domains](#) (EAD) in the same [Metro](#) in order to achieve 99.99% SLA. You can connect your Cloud Interconnects to multiple regions in the same Shared VPC. This diagram shows Dedicated Interconnect in two regions.

## 2) VLAN Attachment

A [VLAN attachment](#) connects your interconnect in a Google point of presence (PoP) to a Cloud Router in a specified Google Cloud region.

## 3) Cloud Router

A [Cloud Router](#) exchanges dynamic (BGP) routes between your VPC networks and on-premises routers. You can configure [dynamic routing](#) between your on-premises routers and a cloud router in a particular region. Each cloud router is implemented by two [software tasks](#) that provide two interfaces for high availability. Configure BGP routing to each of the cloud router's interfaces.

## 4) VPC Global Dynamic Routing

Configure [global dynamic routing](#) in the Shared VPC to allow exchange of dynamic routes between all regions.

### Abbreviation

EAD = [Edge Availability Domain](#)

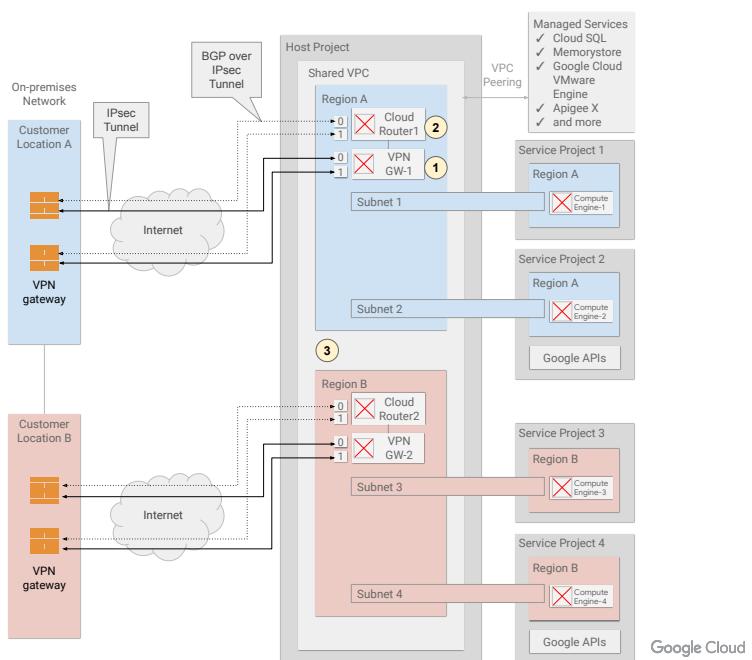

Metro = [Metropolitan Area](#)

# A. Hybrid connectivity to single VPC (or Shared VPC)

A3: HA-VPN to on-premises

## 1) Cloud HA-VPN

The Cloud HA-VPN gateway is used to establish IPsec tunnels to the on-premises VPN gateway over the Internet. HA-VPN offers a 99.99% SLA. You can have multiple HA-VPN tunnels into different regions in the Shared VPC.

## 2) Cloud Routers

Configure [dynamic routing](#) between the on-premises routers and a [cloud router](#) in each region. Each cloud router is implemented by two [software tasks](#) that provide two interfaces for high availability. Configure BGP routing to each of the cloud router's interfaces.

## 3) VPC Global Dynamic Routing

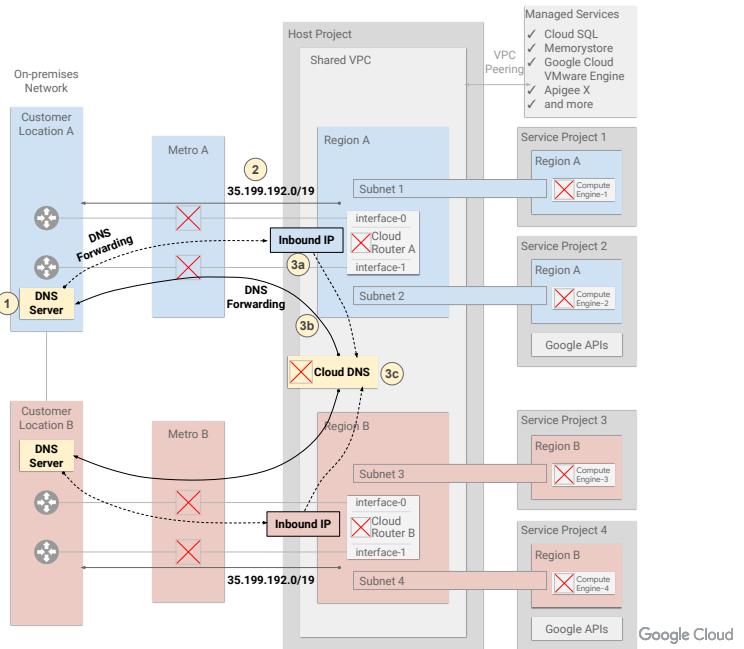

Configure [global dynamic routing](#) in the Shared VPC to allow exchange of dynamic routes between all regions.

A4: DNS

## Overview

In a hybrid environment, DNS resolution can be performed in Google Cloud or on-premises. Let's consider a use case where on-premises DNS servers are authoritative for on-premises DNS zones, and Cloud DNS is authoritative for Google Cloud zones.

For more information, refer to the DNS best practice documentation at [Hybrid architecture using a single Shared VPC network](#).

### 1) On-premises DNS

Configure your on-premises DNS server to be authoritative for on-premises DNS zones. Configure DNS forwarding (for Google Cloud DNS names) by targeting the Cloud DNS inbound forwarding IP address, which is created via the [Inbound Server Policy](#) configuration in the Shared VPC. This allows on-premises network to resolve Google Cloud DNS names.

### 2) Host Project (Shared VPC) - DNS Egress Proxy

Advertise the Google [DNS Egress Proxy](#) range 35.199.192.0/19 to the on-premises network via the cloud routers. Outbound DNS requests from Google to on-premises

are sourced from this IP address range.

### 3) Host Project (Shared VPC) - Cloud DNS

- a. Configure an [Inbound Server Policy](#) for inbound DNS requests from on-premises.
- b. Configure [DNS forwarding zone](#) (for on-premises DNS zones) targeting the on-premises DNS resolvers.
- c. Configure DNS [Private Zones](#) in the **Host Project** and attach **Shared VPC** to the zone. This allows hosts (on-premises and all service projects) to resolve the Prod DNS names.

A5: Private Service Connect (PSC) for Google APIs

Access to all supported APIs and services

## Overview

You can use Private Service Connect (PSC) to access all supported [Google APIs and services](#) from Compute Engine hosts and on-premises hosts; using the internal IP address of a PSC endpoint in the Shared VPC. Let's consider PSC access to a service in **Service Project 4** via the Shared VPC.

## Create a PSC Endpoint

- 1) Choose a [PSC endpoint address](#) (for example, 10.1.1.1) and create a [PSC endpoint](#) in the Shared VPC with a target of "**all-apis**" - which gives access to all supported Google APIs and services. Service Directory automatically creates a DNS record (with DNS name of [p.googleapis.com](http://p.googleapis.com)) linked to the PSC endpoint IP address.

## Access from Compute Engine Hosts

**Compute Engine-4** host in **Service Project 4** can access all supported Google APIs and services via the PSC endpoint in the Shared VPC. Read more about [using an endpoint](#).

- 2) Enable [Private Google Access](#) on all subnets with compute instances that require access to Google APIs via PSC.
- 3) If your Compute Engine clients can use custom DNS names (for example,

1) **storage-xyz.p.googleapis.com**), you can use the auto-created **p.googleapis.com** DNS name. Read more about [using p.googleapis.com DNS names](#).

2) If your Compute Engine clients cannot use custom DNS names, you can create Cloud DNS records using the default DNS names (for example, **storage.googleapis.com**). Read more about [creating DNS records using default DNS names](#).

### Access from On-premises Hosts

On-premises hosts can access all supported Google APIs and services via the PSC endpoint in the Shared VPC. Read more about [using Private Service Connect from on-premises hosts](#).

- 5) Advertise the PSC endpoint address to the on-premises network.
- 6) If your on-premises clients can use custom DNS names (for example, **storage-xyz.p.googleapis.com**), you can create A records mapping the custom DNS names to the PSC endpoint address.
- 7) If your on-premises clients cannot use custom DNS names, you can create A records mapping the default DNS names (for example, **storage.googleapis.com**) to the PSC endpoint address.

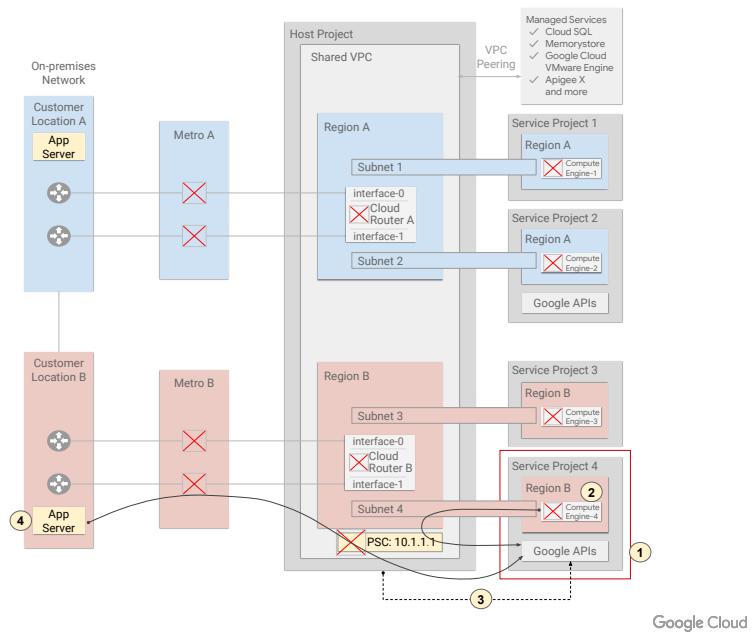

### Abbreviation

Metro = [Metropolitan Area](#)

PSC = [Private Service Connect](#)

# A. Hybrid connectivity to single VPC (or Shared VPC)

## A7: VPC Service Control

## Overview

You can use Private Service Connect (PSC) to access all supported [secure Google APIs and services](#) from Compute Engine hosts and on-premises hosts; using the internal IP address of a PSC endpoint in the Shared VPC. Let's consider PSC access to a service in **Service Project 4** via the Shared VPC.

## Create a PSC endpoint

- 1) Choose a [PSC endpoint address](#) (for example, 10.1.1.1) and create a [PSC endpoint](#) in the Shared VPC with a target of "**vpc-sc**" - which gives access to Google APIs and services that are supported under [VPC Service Control](#). Service Directory automatically creates a DNS record (with DNS name of [p.googleapis.com](#)) linked to the PSC endpoint IP address.

## Access from Compute Engine hosts

**Compute Engine-4** host in **Service Project 4** can access (VPC service control) supported Google APIs and services via the PSC endpoint in the Shared VPC. Read more about [using an endpoint](#).

- 2) Enable [Private Google Access](#) on all subnets with compute instances that require access to Google APIs via PSC.

- 1) If your Compute Engine clients can use custom DNS names (for example, **storage-xyz.p.googleapis.com**), you can use the auto-created **p.googleapis.com** DNS name. Read more about [using p.googleapis.com DNS names](#).
- 2) If your Compute Engine clients cannot use custom DNS names, you can create Cloud DNS records using the default DNS names (for example, **storage.googleapis.com**). Read more about [creating DNS records using default DNS names](#).

### Access from on-premises hosts

On-premises hosts can access all secure Google APIs and services via the PSC endpoint in the Shared VPC. Read more about [using Private Service Connect from on-premises hosts](#).

- 5) Advertise the PSC endpoint address to the on-premises network.
- 6) If your on-premises clients can use custom DNS names (for example, **storage-xyz.p.googleapis.com**), you can create A records mapping the custom DNS names to the PSC endpoint address.
- 7) If your on-premises clients cannot use custom DNS names, you can create A records mapping the default DNS names (for example, **storage.googleapis.com**) to the PSC endpoint address.

### Abbreviation

Metro = [Metropolitan Area](#)

PSC = [Private Service Connect](#)
